and the direction *d E* to *a c*, so that an eye at E or *e* will see only a single image of the sun S. But if S *a* be not parallel to A C, then *d E* will not be parallel to *a c*, and a double image will appear. Suppose, for instance, the sun's course to be in the direction from A towards B; then, before the sun comes to the meridian, the pencil of light S *a* will make with A B an angle S *a* A less than 60°. Consequently, the reflected ray *a c* will make the angle *e a B* less than 60°. But in this case the angle *E d B* will be greater than 60°, and therefore two images will be seen by the eye at E, one in the direction *e a*, and the other in the direction *E d*. The first of these will appear to move with the sun in the direction A B, and the second in the opposite direction B A; they will approach each other until S *a* becomes exactly parallel to A C, when they will coincide; after this, as the angle S *a* A becomes greater than 60°, they will separate, and gradually pass off the field, one at B, and the other at A. Hence it is evident that if A C be in the plane of the meridian, the instant of the coincidence of the two images will be that of apparent noon.

When used as a meridian instrument, the dipleidoscope must be fixed so that one of the reflecting planes, A C, is exactly vertical, and also in the meridian. The latter adjustment may be made by any of the means which suffice for fixing a sun-dial, or for drawing a meridian line: the former, by suspending a fine plumb-line a few feet before the transparent glass, and moving the instrument slowly about the edge A C till the two images of the line become exactly parallel. These are the only essential adjustments; but it is convenient also to fix the instrument so that the lines of intersection of the three planes may be parallel to the axis of the earth's rotation, in order that the sun's greatest altitude above the plane of the instrument at midsummer may be equal to his greatest depression below it at midwinter. On account of the intense light of the sun, the eye must be protected by a coloured glass; and the field of view may be magnified by a small telescope. Three observations should be made; the first, of the instant at which the two images come into contact; the second, of the instant at which they exactly coincide; and the third, of the instant at which they separate. The instrument, if accurately made and fixed, is capable of giving true time within a fraction of a second.

Diploe (Gr. *διπλός*, *I double*). The horny or spongy substance between the tables of the skull.

Diploma (Gr.). Every sort of ancient charter, donation, bull, &c. is comprehended by writers on diplomatics under the name *diploma*. The term is derived from the earliest charters of donation with which we are acquainted, those of the early Roman emperors having been inscribed on two tablets of copper joined together so as to fold in the form of a book. The form and character of the diploma granted

DIPLOMACY

by the sovereigns, prelates, nobles, &c. of modern Europe, varied from age to age; and the knowledge of these variations forms an important branch of the science of diplomacy.

Diplomacy. In a restricted sense, this term is used to express the art of conducting negotiations or arranging treaties between nations by means of their foreign ministers, or written correspondence; but, in its more extended signification, it denotes the whole science of negotiation with foreign states, which embraces:—

1. The law of nations, by which the relations of one state with another are determined both in peace and war.

2. The political principles of individual states, as deduced from a regard to their peculiar interests; and a knowledge of the way in which these interests may be reconciled with, and made subservient to, the law of nations.

3. An acquaintance with the privileges and duties of diplomatic agents.

4. The conduct of negotiations, or the course to be pursued in treating of the interests of different states.

5. The moral and physical statistics of each power.

6. The political and military history of the states having diplomatic relations; and the projects, tendency, and policy of their respective governments.

7. The various systems of government; supremacy, concession, retention, equilibrium, centralisation, confederacy, &c., that may be brought into operation.

8. The art of composing diplomatic despatches.

To this multifarious information the diplomatist should unite the powers of calculation and application peculiar to strong minds—the *tact des convenances*, which may be felt, but cannot be expressed—circumspection, address, and perfect integrity. The combination of these various qualities will procure for the diplomatist such a character for sagacity, rectitude, and straightforwardness, as will sooner or later obtain for him an ascendancy over the minds of others, and give great weight to his opinions.

It must be remembered that the diplomacy of every nation is more or less within the range of casualties; being subject to the variability inseparable from human affairs, the fickleness and passions of man; and the uncertainty of events; an unlooked-for death, a change of ministry, treacherous designs, undue influence from any quarter, a false calculation, corruption: each of these causes may change the policy or course of a government; and this will more or less affect every other government, in proportion to the extent of its influence. In addition to these numerous causes of variation, if ambitious projects be entertained by any great power, diplomacy becomes still more intricate and difficult. Every state desires to be protected against the storm which its rulers imagine they can prognosticate, and of whose bursting they are apprehensive. Again, we must remark that

DIPLOMATICS

the schemes of a government, how admirably soever contrived, have often miscarried, either from subordinate persons or those who are intrusted with putting them in execution having misapplied or misunderstood the instructions of their superiors.

From what has been said, it will be easily understood that, in diplomacy, false estimates are frequently formed of the merits of original plans or designs from looking at their results only. The diplomatist is of course exempted from all responsibility in regard to operations mixed up with the events of war; he is answerable only for the success of his projects under the conditions on which he proposed them.

A diplomatist of moderate capacity, if favoured by circumstances, may accomplish much more than the man of genius who has to contend with adverse fortune; but this difference of success makes no change in their relative ability, and those who are acquainted with the circumstances readily discriminate between sagacity and accident.

Diplomacy has been practised in substance ever since mankind have been formed into independent states, though it is difficult to ascertain the precise period at which the term came into use. The system, however, of the regular and uninterrupted residence of foreign ministers during peace at the European courts, as at present practised, is said to have originated with the cardinal de Richelieu. Before that time embassies had been only sent on special occasions, but attended with much greater show and retinue than has been the fashion in modern times; while the substantial business of states at the neighbouring courts was transacted by agents of a lower stamp and character. Diplomatic agents are now ranked, in Europe, in the following order, according to the regulations of the congress of Vienna: 1. Ambassadors; 2. Envoys extraordinary and ministers plenipotentiary; 3. Ministers resident; 4. *Chargés d'affaires*; 5. Secretaries of legation and *attachés*: the latter, however, have no precise diplomatic character, and are only considered by courtesy as attached to the

Among the best works on this important subject are the *Traité complet de Diplomatie, ou Théorie générale des Relations extérieures des Puissances de l'Europe*, par M. le Comte de Gaden (Paris 1833), 3 vols. 8vo.; and De Wicquefort's *Ambassadeur et ses Fonctions* (Ed. Opt.), 1746, 12 vols. 4to. See also the *Manuel Diplomatique*, by Von Martens (Paris 1825); Flasseau's *Histoire Générale et Raisonnée de la Diplomatie Française*, 7 vols. (Paris 1811); and Von Martens' (senior) *Grundriss einer Diplom. Geschichte der Europ. Staatshandel*, &c. (Hamburg, 8vo.).

Diplomatics. The science of deciphering ancient writings, assigning their date, &c. The name is derived from *DIPLOMA* [which see]. Writings of earlier date than the fifth century were mostly on the leaves of the papyrus, or

DIPLONEURANS

Biblos Egyptiaca. Parchment appears to have been first generally used in that century; and the oldest documents bearing the character of diplomas which we possess do not extend to a higher antiquity. Not long after the general adoption of parchment, a variety of substances and colours began to be used in writing, as vermilion, purple, gold, and silver but this sumptuous fashion did not long remain in use. The science of diplomatics teaches the different styles and forms adopted in ancient public documents; the titles, rank, &c., of public officers whose names are subscribed to them; the knowledge of the materials used in writing in different ages, of the different characters used in successive periods and in various countries, and the several kinds of diplomas or public instruments.

This science is said to owe its origin to a Jesuit of Antwerp, named Pabebroch, who devoted himself to the research and exposition of old diplomas about the year 1676; but the honour of having established it on a sure foundation is due to Mabillon, whose learned work, *De Re Diplomatica*, was given to the world in 1681. The principles laid down by Mabillon, however, were more fully developed about the middle of last century, in the *Nouveau Traité de Diplomatique*, which has left little to be done by subsequent labourers in this field beyond the duty of translation, compilation, or abridgement. We subjoin a list of the most important works on this science, arranged according to their dates of publication; from which it will be seen that the French and Germans have prosecuted this science with an energy and enthusiasm to which, considering its importance, our national literature presents a humiliating contrast. Besides the work of Pabebroch above referred to, entitled the *Propyleum*, there are: Mabillon, *De Re Diplomatica*, 6 vols. fol. (Paris 1681), to which a supplementary vol. was added in 1704; *Historia Diplomatica*, by Maffei, 4to. (Mantua 1727: this work may be regarded as merely a supplement to Mabillon); *Chron. Waltheri Lexicon Diplom.* 3 vols. fol. (Göttingen 1746-7); Hermann von Teutschenbrunn, *Commenta. de Re Diplom.* Regum, &c. 4to. (Nuremberg 1746); *Nouveau Traité de Diplomatique*, by the Benedictine monks Toussaint and Tassin, 6 vols. 4to. (Paris 1750-65); De Vaine's *Dictionnaire Raisonné de Diplomatique*, 2 vols. 8vo. (Paris 1774: this work is intended chiefly to aid beginners in the science); Gatterer, *Abriß der Diplomatie*, 8vo. (Göttingen 1798); Schönmann's *Proliis de finibus Artis Diplom.* *Pract. Regundis*, and his *Versuch eines Vollständ. Systems der Allgem. besonders ältern Diplomatie*, 8vo. (Göttingen 1802).

Diploneurans, Diploneuræ (Gr. διπλός, double, and νῆρ, nerve). A name applied by Rudolphi to that division of the animal kingdom comprehending the species which have two nervous systems, viz. the ganglionic or sympathetic, and the cerebro-spinal; the series

DIPPING NEEDLE

so designated corresponds with the *Vertebrata* of Cuvier.

Diplopia (Gr. διπλός, and ὄπτος, I see). Double vision. This affection occasionally is symptomatic of nervous irritability, worms, indigestion, hysteria, &c.

Diploptera (Gr. διπλός, and πτερόν, a wing; double-winged). The name of a division of Aculeate Hymenopterous insects, comprising those species of wasp which have the upper wings folded or doubled up longitudinally when at rest.

Diplozoon (Gr. διπλός, and ζῶν, animal; double animal). The name of a very singular parasitic worm, which infests the gills of the bream, and which appears to be formed of two distinct bodies united in the middle, so as to present the appearance of a St. Andrew's cross, each half of the animal containing precisely the same organs, viz. an alimentary canal, a sanguiferous and a generative system.

Dipneumoneans, Dipneumones (Gr. δίς, and πνεύμων, a lung; two-lunged). A term applied to a section of spiders (*Araneida*), including those which have only two pulmonary sacs.

Dippel's Oil. An empyreumatic oil, produced during the destructive distillation of bone.

Dipper. A name commonly given to the water-ouzel and other species of the genus *Cinclus*.

Dipping Needle. An instrument for showing the direction of one of the components of the earth's magnetism. Its axis is at right angles to its length, and passes as exactly as possible through its centre of gravity, about which it moves in a vertical plane. When a needle thus mounted is placed anywhere not on the magnetic equator, it dips, or points downwards; and if the vertical plane in which it moves coincides with the magnetic meridian (which is always known by means of a variation compass), the position which it assumes shows at once the direction of the magnetic force; and the intersection of two or more directions, found by making the experiment at different places, indicates the place of the magnetic pole. Though the principles on which the dipping needle acts are abundantly simple, its practical construction is found to be exceedingly difficult. It must be accurately balanced on its axis; the axis must be placed exactly horizontal; the friction must be diminished to the utmost extent possible; and the adjustments can only be made when the needle is perfectly free from magnetism, and so secured from the effects of the magnetic influence of the earth. It must be subsequently magnetised, and during this process much care is required to guard against derangement. The simplest construction is represented in the following figure. The needle D d consists of a flat oblong piece of steel, tapering to a point at both ends, and having a slender cylindrical axis passed through its centre of gravity. The axis moves freely in circular holes

DIPROTODON

needle in the lateral horizontal bars H h, which support a vertical circle C C, graduated for the purpose of showing the inclination of the needle to the horizon. The stand S T, to which the circle is fixed, is provided with levels, and adjusted to horizontality by means of screws. But in the most improved form of construction of the dipping

needle, the axis, instead of being a cylinder, is a knife edge, resting perpendicularly, like the supports of a pendulum, on two agate planes. A needle thus supported, however, must necessarily make small oscillations; consequently it must be so adjusted that when it points in the direction of the magnetic force, the knife edges may be perpendicular to the agate planes. The mean value of the angle of the dip must therefore be known previously to its construction; but it is the best adapted, on account of its delicacy, for ascertaining the minute variations of the dip at the same place. The angle of the dip, like that of the variation, changes its value even at the same place, following of course the motion of the magnetic poles, which, from the observations made by Scoresby, Parry, Ross, and others in high latitudes, appear to have a motion westward, the annual amount of which is about $11' 4''$. In the summer of 1831 Commander Ross, in an excursion from the vessel in which his party were so long detained in the polar seas, reached a spot on the continent of North America which had been calculated to be the position of the magnetic pole. There he found the dip of the needle to be $89^\circ 59'$, within one minute of the vertical; and compass-needles suspended in the most delicate manner possible exhibited no polarity whatever. The latitude of this spot is $70^\circ 8' 17''$ north, and its longitude $96^\circ 46' 45''$ west. (For a description of some other forms of the dipping needle, see Brewster's *Treatise on Magnetism*.) [MAGNETOMETER.]

Diprotodon (Gr. *dis*; *opros*, first; and *odon*, tooth). A genus of Marsupials found in the pliocene caves of Australia, which presents the closest analogy in its dentition to the existing Kangaroos (*Macropus*), but with an occultant relationship with the herbivorous wombat. The skull measures three feet in length. The limbs were modified to present a more pachydermal character than those of the existing *Macropida*. The dental formula is

$$\begin{array}{c} 3-3 \\ 1-1 \end{array} \quad \begin{array}{c} 1-1 \\ 1-1 \end{array} \quad \begin{array}{c} 4-4 \\ 4-4 \end{array} \quad 28.$$

Dipsacaceae (Dipsacus, one of the genera). In Botany, a natural order of herbaceous Exogens, of the Campanal alliance, chiefly inhabiting the south of Europe. They are nearly allied to *Compositae*, but differ in their stamens being distinct, and their ovules being pendulous. They are distinguished from *Calyceae* by the latter having connate anthers and alternate leaves; and from *Valerianaceae* by their capitate flowers, and the presence of

DIPTEROCARPUS

albumen. Their properties are unimportant. *Dipsacus Fullonum*, the Fuller's Teasel, is employed mechanically, for the sake of the hard stiff bracts of its flower-heads, in the process of dressing woollen cloths.

Dipsas (Gr. a serpent whose bite caused thirst). This term has been applied by Laurenti to a genus of Colubrine serpents; and by Dr. Leech to a genus of fresh-water Bivalves, intermediate to *Unio* and *Anodonta*.

Dipteraceae. A natural order of arborecent Exogens, only found in India and the Indian Archipelago. They belong to the Guttiferal alliance, in which they are distinguished by their simple alternate leaves with large stipules, their symmetrical flowers, unequal permanent calyx, bearded anthers, and one-celled one-seeded fruits. Blume traces an affinity with *Clusiaceae* in their resinous juice, compound superior ovary, drupaceous fruit, numerous long anthers, irregular coloured calyx, and single exalbuminous seed; but from this order the stipules and the aestivation of the corolla abundantly distinguish them. The order is chiefly marked by the enlarged foliaceous unequal segments of the calyx investing the fruit. To it belongs the Camphor-tree (*Dryobalanops Camphora*), which also yields the camphor oil of Borneo and Sumatra; while other species yield pitch.

Dipteral (Gr. *δίπτερος*, with two wings). In Architecture, a temple which has a double row of columns on each of its flanks.

Dipterans, **Diptera** (Gr. *δίπτερος*). An order of insects having for their main and most conspicuous character two wings only corresponding to the anterior pair, and two short clubbed appendages, called *halteres* or *balancers*, and which seem to be the rudiments of the posterior pair in four-winged insects. The Dipterans are also distinguished by having the mouth in the form of a sucker, composed of from two to six lancet-shaped elongated scales, enclosing a canal upon the upper surface of a fleshy tongue or proboscis. The larvae or maggots of the Dipterous insects have frequently a membranous head; and always have the stigmata, or breathing pores, confined to the second and terminal segments of the body. In some species, as the blow-fly, the eggs are hatched within the body of the parent; in others, as the forest-fly (*Hippoboscæ*), the larva undergoes its metamorphosis in the parent's body, and the young are excluded in the form of pupæ.

Dipterocarpus (Gr. *δίπτερος*, and *καρπός*, a fruit). A genus of *Dipteraceae*, consisting of lofty trees of the Indian islands, abounding in resinous juice which is used medicinally and for burning in torches. They have leathery simple leaves, and bear clusters of large fragrant flowers. The calyx is divided into five unequal segments, two of which become very large and leaf-like, forming wings to the one-seeded fruits. *D. laevo* yields a thin liquid balsam called *wood oil*, which is used as a substitute for paint, and mixed with dammer is

DIPTERYGIANS

aluable in preserving timber from the ravages of the white ant. This wood oil is imported as a substitute for Balsam of Copaiba, which much resembles.

Dipterygians, Dipterygia (Gr. *δῖς*, and *ῥέπυς*, a fin; two-finned). A family of fishes comprehending those which have but two fins.

Dipteryx or Dipterix (Gr. *δῖς*, and *πτερυξ*, wing). A genus of *Leguminosæ*, consisting of large trees found in the forests of Brazil, Guiana, &c., and being one of the few genera of this order in which the fruit is one-seeded and indehiscent. *D. odorata* yields the coumarincented Tonquin or Tonka Bean, employed by perfumers, and for scenting snuff. This tree grows sixty or eighty feet high, and its fruit bears some resemblance to that of the almond. *D. eboensis* yields an excessively heavy yellowish timber, and its seeds contain a large quantity of fatty oil.

Diptote (Gr. *δῖς*, and *πτερίς*, a case). In grammar, a name applied to those nouns which have only two cases.

Diptych (Gr. *δίπτυχος*, two-fold). Among the Romans, a tablet of wood, metal, or other substance, used for the purpose of writing, and folded like a book of two leaves: when the book consisted of several leaves, it was termed *καλιδίπτυχος*, or *manifold*. The diptychs of antiquity were employed especially for public registers. The sacred diptycha of the Greek church were double catalogues, containing on one side the names of the living, on the other those of the dead, which were rehearsed during the office.

Dipus (Gr. *δίπους*, two-footed). The general name for the Jerboa or Rodent animals, in which the hind-legs are disproportionately developed, and chiefly serve for locomotion. The numerous species referable to the Linnæan genus are now divided into the subgenera *Alactaga*, *Gerbillus*, *Dipus* proper, &c.; and form the family *Dipodidae*; the *Gerbilli*, however, are more nearly allied to the *Muridae*.

Dipyre (Gr. *δίπυρος*, from *δῖς*, and *πῦρ*, fire). A silicate of alumina, lime and soda; composed of 53·8 per cent. of silica, 26·2 alumina, 9·5 lime, and 10·5 soda. It occurs in greyish or reddish-white translucent or transparent fascicular masses and in slender four-sided prisms, which are indistinctly formed and rounded at the ends like grains of wheat. The name has reference to the double effect produced upon the mineral by fire, which first renders it phosphorescent, and then fuses it. Dipyre is found in clay-slate near Mauldon, in the Western Pyrenees, and in the valley of Castillon.

Direct (Lat. *directus*, part. of *dirigo*). In Music, a character used at the end

of a staff, to direct the performer's notice to the succeeding note at the beginning of the following staff.

Direct Acting Engines. Those in which the motion of the piston is communicated directly from the head of the piston rod, through the connecting rod, to the crank, without the intervention of side levers or a balance

DIRK

beam. In the modern direct acting engines an attempt has been made to do away with the fly-wheel, and to apply the steam directly to the resistance.

Director. A common surgical instrument: it is generally made of silver, and resembles a grooved probe. Its use is to direct the knife, and protect the parts underneath from its edge or point.

Directors. In Commerce, the name given to the individuals composing the board of management of a joint-stock company; as of the bank of England, &c.

Directory (Fr. *Directoire*). In French History, the name given by the constitution of 1795 to the executive body of the French republic. It consisted of five persons, called *directors*, who were selected by the council of elders from a list of candidates presented by the council of five hundred. One of these directors retired every year, and was succeeded by another elected on the same principle. To the Directory was intrusted the superintendence of the home and foreign departments, the finances and the army, and the appointment of the ministers of state and other public functionaries. Its policy was at first moderate and conciliatory; but after a short interval it had recourse to measures which produced widespread dissatisfaction, and it was at length overthrown on the ascendancy of Bonaparte after an existence of four years. The most complete of the many works on its history, is De Barante's *Histoire du Directoire*, 1856.

DIRECTORY. A book containing the names of the inhabitants of a town, arranged in alphabetical order, together with their places of abode, &c. It is likewise applied to a book containing directions for public worship, or other religious services.

Directrix. In Geometry, usually denotes a right or curved line which serves for the description or definition of a curve or surface. The directrix of a conic is a right line perpendicular to the axis whose distance from any point on the curve bears a constant ratio to the distance of the same point from the focus. [CONIC SECTIONS.] Quadric surfaces have also directrices possessing analogous properties. [FOCUS.] When a surface is conceived to be generated by the motion of a line, right or curved, which always rests on other fixed lines, the latter are sometimes also called *directrices*, but more frequently *directing lines*, or simply *directors*; the former being distinguished as the *generator*. [RULED SURFACE.]

Dirge (a contraction of Lat. *dirige*, used in the old formula of the Catholic service for the dead—*Dirige Domine Deus*). A funeral song or hymn.

Dirigents. A term applied in old Pharmacy to certain ingredients in prescriptions which were supposed to *direct* the operation of the others to some particular organ.

Dirk (Ger. *dolch*, Swed. *dolk*). A short sword, of dagger form, used by midshipmen and naval cadets in the Royal Navy.

DIRT BED

Dirt Bed. A remarkable deposit, in the upper oolites of England, of ancient soil containing the remains of trees that once grew upon it. This bed is from twelve to eighteen inches thick. It is of a dark brown or black colour, and contains a large proportion of earthy lignite. Rounded stones from three to nine inches in diameter are distributed through it, and the silicified trunks of coniferous trees like *Zamia* are buried in it. At Lulworth Cove this bed is found inclined at an angle of 45° to the horizon. At some places the phenomena are more complicated than at others, but the general facts are the same throughout. The position of the dirt bed is in the Lower Purbeck series near the top of the middle secondary or mesozoic rocks. Several inches of this black earth or loam containing fragments of fossil wood and the roots of ancient trees may be traced for many miles, marking clearly the position of ancient lands at the period of deposit.

Besides the bed commonly recognised by geologists as the *dirt bed*, there are in various places in other deposits indications of the same kind, but none are so complete and characteristic. The coal measures of some parts of British North America are perhaps among the richest localities of similar phenomena out of England. [OOLITE STRATA AND OTHER BED.]

Disability. In Law, signifies a state which renders a person incapable of enjoying certain legal benefits; as the state of an alien renders him incapable of taking lands, that of infancy of making valid contracts, and so forth. Disability, it is said, may happen in four ways; by the act of the ancestor, of the person, of God, or of the law.

Disc or Disk (Lat. *discus*). In Astronomy, the face of the sun, moon, or a planet, such as it appears to us projected on the sky. The forms of the celestial bodies being spherical, or nearly so, their projections are circular planes. When viewed through a telescope, the fixed stars also present the appearance of discs; but as these are due entirely to the effects of diffraction, which varies inversely as the aperture, they are termed *spurious discs*.

Discharge. In Architecture, this term is used to signify the relief, or distribution of a weight, or load to be borne; thus, discharging arches are used in a wall over a lintel, or an opening, to discharge them of the weight which they would otherwise bear.

Disciple (Lat. *discipulus*). Literally, one who learns the principles of any science or art from another; but the term is used more particularly to signify the followers of any teacher or philosopher whose spirit they have imbibed along with a knowledge of his peculiar tenets.

Discipline (Lat. *disciplina*). Signifies, primarily, instruction or government; but it is applied figuratively to a peculiar mode of life, in accordance with the rules of some profession or society. It is also used to designate the punishment employed in convents, and those which enthusiasts undergo or inflict upon themselves by way of mortification.

DISCOUNT

Discipline, Book of. In the church of Scotland, a common order, drawn up by the General Assembly in 1650 for the reformation and uniformity to be observed in the discipline and policy of the church. In this book episcopal government is set aside, Kirk sessions are established, the observance of saints' and other holy days is condemned, and regulations for the internal government of the church are prescribed. It is called the *First Book of Discipline*.

Discipline of the Secret or Disciplina Arcani (Lat.). A name given by theological writers to a system pretended to have been in force in the primitive church, by which its most important and mysterious doctrines were concealed from the mass of believers, and fully developed only to a select class.

Disclaimer. In Law, a plea containing an express denial or renunciation of some claim alleged to have been made by the party pleading. The term is also applied to the act of one who renounces or refuses to accept a gift or devise made to him of land or other property, and generally to the waiver of any claim.

Discoboles (Gr. *δισκοβόλος*, *quoit throwing*). In Ichthyology, this word is applied to a family of pectoral or sub-brachian fishes, comprehending those which have the ventral fins confluent, and forming a suctorial disc beneath the throat.

Discoid (Gr. *δισκοειδής*, *disc-shaped*). This term is applied to those univalve shells of which the whorls are disposed vertically on the same plane, so as to form a disc; as in the *pearly Nautilus* and *Planorbis*.

Discontinuance. In Law, an injury to real property, which consisted in the keeping out the rightful owner of an estate by a tenant whose entry was at first lawful, but who wrongfully retained the position afterwards: as, where tenant in tail made a feoffment in fee-simple for life or in tail. In this case the heir in tail, remainder-man, or reversioner, was out to his writ, i.e. compelled to have recourse to REAL ACTION; but the effect of discontinuance was abolished by stat. 3 & 4 Wm. IV. c. 27, sect. 39: and the abstruse and technical learning connected with this subject has now become obsolete.

Discord (Lat. *discordia*). In Music, a chord or harmony which produces for the moment an unpleasant effect, or at least which requires to be followed, or, as it is termed, resolved, by a concord following, in order to satisfy the ear.

Discordia. [ERIS.]

Discount. An allowance made for the payment of money before it becomes due. To favour neither party, the discount on a sum of money due a year hence should be the difference between that sum and its *present value*; that is to say, the sum which, in a year's time, at the ordinary rate of interest, would yield the same amount. Thus the discount on a bill of £101, due a year hence should be 4*l.*, money being worth four per cent. Bankers and mercantile men, however, are allowed the advantage

DISCOUNT

of calculating discount as simple interest: they would charge 4l. 3s. 2½d., a year's interest on 104l. at four per cent., for discounting the bill in question.

Discount. In Political Economy. A person possessed of abilities, opportunities, and character necessary for carrying on an industrial occupation may be deficient in the capital requisite for accomplishing his purpose. On the other hand, some other person, tastes or whose powers are inadequate for engaging in any other occupation than that to which he is habituated, may have accumulated capital, and desire to employ it for his advantage. As capital is desirable, and the beneficial investment or employment of capital is desirable to both these parties respectively, it will not be difficult to conceive that means should be discovered for bringing these parties together, and for satisfying their several wishes; and as modern societies are large, and the demand and supply of capital may not on this account be easily brought into communication, the further need of some intermediary or other who will engage to find employment for capital, and capital for employment, will not long wait for satisfaction. The person who supplies capital will require some advantage for his loan, or, as Mr. Senior has said, 'a reward for his abstinence' in not employing his capital on his personal gratification; and again the borrower of capital is willing, because he discovers a further profit on the extension of his energies by means of additional capital, to promise the reward or remuneration required. The amount or remuneration demanded for the advance is determined by the joint competition of borrowers and lenders, and is known generally by the name of *interest*. [**INTEREST.**]

Discount is only another form of interest. Investments of capital are either made for some long or permanent space of time, or are intended only for short or recurrent periods. The latter are generally made under the conditions of discount; that is, the interest to be paid at the end of the period is deducted from the amount advanced at its commencement. To borrow 100l. at four per cent. for three months, and to pay 101l. at the end of the period, does not, for the purpose of illustration, differ substantially from taking 99l. at once, under the promise to pay 100l. at the end of three months. The former transaction would be called *interest*; the latter is the process of discounting a bill of exchange, or other obligation, the date of payment of which is deferred.

The intermediaries to the borrower and lender in mercantile transactions are bankers, bill-discounters and the like. These functionaries employ to some extent their own capital, to a far larger extent the capital of others, in advances upon loan to borrowers; the charge for the accommodation being the discount. The motive inducing the deposit of cash or capital with a banker or bill-discounter is either the convenience of a banking account,

DISCRETE

and the privilege which the customer of a bank has in securing assistance either by loan or by discount on his paper; or a direct participation in the profits of the advances, by an arrangement allowing depositors a variable rate of interest on their deposits. This method of accumulating capital for banking purposes is especially characteristic of modern or joint-stock banking; and the funds available for commercial purposes, but derived from deposits, are in such banks many times more than the proprietors' capital.

The customary rates of interest and discount have a tendency to equality. But in the ordinary course of trade, the rate of discount is slightly lower than the rate of interest, because there is an advantage in the fact that the loan is rapidly repaid, bills being generally drawn for three months only, and the competition of lenders lowering the rate of discount to the minimum which the supply will permit. When, however, the money market is said to be *tight*, that is when there is a temporary excess of borrowers, either because it is necessary to meet extraordinary obligations, or because speculation is active, or the foreign exchanges are adverse, or the currency is contracted by the exportation of specie, the rate of discount is higher than the rate of interest; the competition of borrowers raising the rate to the maximum which can be extracted from their necessities.

The rate of discount for the time being is determined generally by the directors of the bank of England. This establishment is, however, affected by the same influences which raise or depress the rate in the open market. The Bank itself discounts bills, and if it kept the rate above that which prevails elsewhere, its own profits would diminish; while on the other hand, were its rate less than that at which private bill-discounters can afford to make their advances, the pressure for accommodation would diminish its resources. The publication, therefore, of its minimum rate of discount is always a matter of importance to merchants, because it indicates what, in the opinion of a body of the most eminent men of business, is the rate at which loans can be made for commercial purposes. [**EXCHANGE, BILL OF; PANIC; MONEY MARKET.**]

Discourse (Lat. *discursus*). In Rhetoric, a series of sentences and arguments arranged according to the rules of art. In Logic, this term is applied to the third operation of the mind, commonly called *reasoning*. [**LOGIC.**]

Discovery. In Law, the act of revealing or disclosing any matter by a defendant in his answer to a bill in chancery. [**CHANCERY.**]

Discase or **Discrasite** (Gr. *dis*, and *κρᾶσις*, *mixture*). Native antimonide of silver. It occurs crystallised and in grains. The colour is silver-white with a metallic lustre.

Discrete (Lat. *discretus*, *separated*). A term in Mathematics opposed to *continuous*. Thus ordinary numbers are *discrete quantities*, being formed by the successive addition of

DISCRIMINANT

units. Again, four numbers are said to form a *discrete proportion* when the ratio of the first to the second, although equal to that of the third to the fourth, differs from that of the second to the third. The numbers 2, 3, 4, 6 possess this property; whereas 2, 4, 8, 16 are *continued proportionals*.

Discriminant (Lat. *discrimino, I separate*). The resultant of the system of equations, formed by equating to zero the several first derived functions of a given quantic, is called the *discriminant* of that quantic; since, when it vanishes, the quantic may always be expressed as a quadric in $(n-1)$ variables linearly related to the n original ones. [EXAMINATION.]

In the case of the ternary quadric

$$u = (abcd ef \mathfrak{I} x, y, z),$$

the discriminant being the resultant of the system

$$\frac{1}{2} \frac{du}{dx} = ax + fy + ez = 0,$$

$$\frac{1}{2} \frac{du}{dy} = fx + by + dz = 0,$$

$$\frac{1}{2} \frac{du}{dz} = ex + dy + cz = 0,$$

is the symmetrical determinant

$$\begin{vmatrix} a & f & e \\ f & b & d \\ e & d & c \end{vmatrix}$$

The vanishing of this discriminant indicates that the conic $u=0$ breaks up into a pair of right lines, in other words possesses a double point.

From the properties of the resultant of a system of quantics [RESULTANT], we at once conclude that the discriminant of an m -ary n -ic, that is to say of a quantic of the n^{th} order in m variables, is a homogeneous function of the coefficients of the *degree* $m(n-1)^{m-1}$, and of the *weight* $n(n-1)^{m-1}$; it being understood that the coefficient of any term of the quantic is affected with a suffix equal to the exponent of the power of one of the variables x in that term.

Every equation with one unknown term may be converted into a binary quantic, and consequently has a discriminant. The latter, in fact, is the product of the squares of all the differences between any two roots of the equation, and consequently vanishes identically whenever the equation has two equal roots. The discriminant, it may be observed, lastly, is always an invariant of the quantic. [INVARIANT.]

Discus (Lat.). The ancient quoit, which consisted of a heavy circular mass of iron, sometimes perforated in the middle. In the ancient game, the players aimed at no mark, but simply tried to throw the quoit to the greatest possible distance. In the Cabinet des Antiquités of Paris, a discus is preserved in which holes are provided for the thumb and fingers. The practice of throwing discs is mentioned by Homer amongst the sports which occurred at the funeral of Patroclus; and Iphidare celebrates

DISEASE

Castor and Iolaus as skilful throwers of the disc.

Discontent (Lat. *discutio, I disperse*). Remedies which repel or resolve tumours.

Disease. Any morbid state of the body generally, or of any particular organ or part of the body, is called a *disease*. By medical writers the term *disease* is defined as implying 'a deviation from the natural and healthy actions of the whole system or of any individual part;' and they are in the habit of designating certain forms of disease by the following terms, namely: *Acquired*, which are not congenital or hereditary, but derived from causes evidently operating after birth. *Acute*, which are severe, but of comparatively short duration. *Asthenic*, attended by manifest depression of the vital powers. *Chronic*, which are of long duration. *Congenital*, which are born with the individual. *Constitutional*, which more or less affect the whole system. *Contagious*; this term should be confined to those diseases only which are communicable from one to another by *contact*, either personal or intermediate; it is presumed, for instance, that the plague is a truly contagious disease, and that it can be transferred from one individual to another only by actual bodily contact, or through the medium of bedclothes or articles of apparel. The term *contagious disease* is, however, often misapplied to those which are *infectious*, or communicable through the medium of the atmosphere. *Endemic*, diseases which are either peculiar to particular places, or which are especially prevalent in certain districts only. *Epidemic*, diseases which are generally diffused over a whole country; they may generally be traced to atmospheric causes, and are commonly of an infectious character: influenza and cholera often prevail in this way. *Erythematous* are those diseases which are accompanied by an eruptive fever, such as measles, smallpox, &c. *Hereditary* diseases are such as prevail in families, and are transmitted by parents to their offspring; gout and scrofula furnish examples. *Idiopathic* or *primary* diseases are those which are not dependent upon or symptomatic of others; certain affections of the head, for instance, may arise immediately from disease of the brain, or they may be medietely connected with disordered states of the stomach: the former are idiopathic, the latter *sympomatic*. *Inter-current* diseases are those which arise in individuals from incidental causes during the prevalence of endemic or epidemic sickness. *Intermittent* diseases are marked by a regular cessation and recurrence of symptoms; the patient, during the interval, being, to all appearance, free from disorder: the various forms of ague are characteristically intermittent. *Local* diseases are opposed to those which are constitutional; they are presumed to be limited to some particular organ: the term *chronic disease* is sometimes misapplied in this sense. *Malignant* diseases are those which are of a highly dangerous and intractable character,

DISINTEGRATION

and the symptoms of which are generally very formidable from the first; various forms of fever, rapidly depressing the vital energies, are said to assume a malignant type: hence also the term *malignant*, as generally applied to the Asiatic cholera. Local diseases are frequently malignant, such as cancer and ill-conditioned ulcers: all these are opposed to the *mild* forms of the same maladies. *Periodical*, diseases which recur at fixed periods, as in autumn, winter, &c. *Puerperal*, diseases incident to women soon after childbirth. *Specific* diseases are those which are marked by some disordered vital action not belonging to disease in general, but peculiar to the individual case. *Sporadic* diseases are those arising from adventitious causes affecting the individual. *Sthenic* diseases are marked by the activity of the vital powers, directly opposed to those which are asthenic.

Dr. William Farr some years ago proposed to apply the term *zymotic* to an extensive class of diseases which he probably regarded as produced by fermentation (from the Greek word *zymos*, to ferment). The term is perhaps more correctly applicable to diseases caused by paludal or animal decompositions, and in this way it has been used when speaking of fevers and of the effects of specific animal poisons. Its application has, however, been lately extended to diseases arising from scarcity of food, from unwholesome food, and even cases of scurvy and of worms.

Disfranchisement (Lat. *dis*; Teutonic, *frank*, *free*). The deprivation of the rights and privileges of free citizenship. The term is chiefly applied in the present day to the act which deprives a borough of the right of returning representatives to parliament.

Disinfectants. Substances which destroy infectious and contagious poisons. Many articles formerly considered as possessing these properties are now known to be ineffectual, such as the fumes of vinegar, of burnt resins, of aromatic woods, and certain essential oils; these, however, only cover bad odours. The real disinfectants comprise a few of the gaseous acids, but nearly all of these have been superseded by the peculiar powers of *chlorine*.

Disinfecting Liqueur. Solutions of chloride of soda and of chloride of lime are known under this name. Labarraque's Disinfectant is a solution of hypochlorite of soda. Sir W. Burnett's Disinfectant is a solution of chloride of zinc.

Disintegration (Lat. *dis*, and *integer*, *whole*). The gradual wearing away of a rock by ordinary atmospheric action. All rocks are subject to this action, some wearing away evenly and regularly, and showing little sign of the change they undergo; others, such as granite, wearing very irregularly, owing to the unequal hardness of the rocks. Some of the Shetland Isles present magnificent specimens of the wear and tear of granite. On the west of Maiklo Roe the softer reins have mouldered away, while the firmer rock which included

DISK

them has remained unaltered; and in this way long narrow ravines are laid open which give access to the waves. The singular cluster of rocks at Hillswickness, which has been compared, when seen at a distance, to a small fleet of vessels with spread sails, also affords a good instance of granitic disintegration. Lime-

Hillswickness.

stones sometimes disintegrate with great irregularity, but more frequently they form into caverns, the water eating them out. The disintegration of rocks by the seaside is very marked and often very instructive.

The action of weather is greatly helped when the climate is such as to admit of frequent alterations of temperature above and below the point at which water attains its greatest density (39° Fahr.). It is also well seen where ice is common in summer on account of the great elevation of the land. Thus, in mountains of great elevation this force is often exemplified.

Disjunctive. In Grammar, a conjunction which disjoins the sense of the connected sentences, as, 'He is either wicked or foolish,' 'They are neither wise nor brave.'

Disjunctive Proposition. In Logic, a proposition compounded of two or more categorical propositions, so stated as to imply that some of them must be true: thus, 'Either A = B, or C = D.' A disjunctive, in which the two propositions are not naturally connected together in such a manner as to warrant their being proposed as alternatives, is nugatory and absurd in sense, although not incorrect in logical form. If one or more of the categorical antecedent propositions be denied, we infer that the remaining one, or, if there are more than one, some one of those remaining, is true: e.g. 'Either A = B or C = D; but A is not equal to B, therefore C = D.' A poem is either good, bad, or indifferent: but it is not good; therefore it is bad or indifferent. There are different forms of the *disjunctive syllogism*, founded on the disjunctive proposition.

Disk (Gr. *diskos*). In Botany, a term applied to certain bodies or projections, situated between the base of the stamens and the base of the ovary, but forming part of neither, and taking a variety of forms, the most common of which are those of rings or scales. The disk is usually supposed to consist of rudimentary stamens, since an anther has been noticed to grow from that of *Peonia Moutan*, and in other cases manifest indications are observable of a tendency to assume the form of those organs.

DISLOCATION

Dislocation (Lat. *dis*, and *locus*, a place). A surgical term, synonymous with *luxation*. 'When the articular surfaces of bones are forced out of their proper situation, they are said to be dislocated or luxated. A considerable share of anatomical knowledge is required to detect the nature of these accidents and it is much to be lamented that student neglect to inform themselves sufficiently upon the subject.' (Sir A. Cooper's *Surgical Essays*, i. p. 2.)

Dispart. In Gunnery, half the difference between the diameter of the base ring at the breech of a gun and that of the swell of the muzzle.

Dispensary (Lat. *dispensare*, to distribute). A place where medicines are made up and distributed; but the term is used more generally for a charitable institution, where the poor are supplied with medicines and advice. 'Institutions of this nature are of comparatively recent origin; though they are now to be met with in every town of any importance both in this country and on the Continent. In London there are one or more dispensaries in each district; and to every dispensary there are always attached one or more physicians, surgeons, and apothecaries, whose duty it is respectively to prescribe and dispense medicines to the poor, and to visit them in their own houses in the event of their being too ill to attend personally at the institution. In most cases dispensaries are supported by voluntary contributions.'

Dispensation. In Law, a license granted by the bishop to a clergyman within his diocese to omit some particular of his duty; as, to hold two or more benefices, or to reside out of his parish. In the church of England the power of dispensation has been very strictly limited by recent legislation. The name is peculiar to ecclesiastical law, and was formerly applied to the licenses granted by the papal authority for several purposes; as, to marry within the prohibited degrees, &c.

Dispensatory. A word synonymous with *Pharmacopœia* [which see]; signifying a book which describes the history, preparation, and composition of medicines.

Dispensing Power. In English Law, it was held by early authorities, that the king had a right to *dispense* with the penalty on *mala prohibita*, things forbidden by law and not by moral obligation; whence the claims of James II. to *dispense* with tests against Roman Catholics and Dissenters, which contributed to his overthrow.

Dispersion (Lat. *dispersio*). In Optics, a term used to denote the angular separation of the constituent rays of light when decomposed by the prism. In consequence of the unequal refrangibility of the different rays, a beam of light admitted through a small hole or slit in the shutter of a darkened room, and refracted by passing through a prism, forms an elongated image or spectrum; the red rays, which are the least refracted, occupying one end of the spectrum, and the violet rays, which suffer the

DISPOSITION

greatest refraction, occupying the other end. The rays therefore, after refraction, are no longer parallel; so that the *index* of refraction (or the ratio of the sine of incidence to the sine of refraction) is different for each ray; and the difference of the indices for the extreme rays is called the *dispersion* of the light.

Sir Isaac Newton, who first examined the prismatic colours, was led by some imperfect experiments to suppose the dispersion proportional to the refraction; but it was soon discovered that although the colours in spectra formed by prisms of different substances are always arranged in the same order, they do not occupy the same relative lengths—a prism of flint glass, for example, giving proportionally less red and more violet than a prism of crown glass; and that substances, for which the index of refraction of the middle ray of the spectrum is nearly the same, produce spectra of different lengths, or different amounts of dispersion. It is on this property, namely, the irrationality of the refractive and dispersive powers of different substances, that the methods of forming achromatic lenses depend: had the supposition of Newton been correct, it would have been impossible to produce an image by refraction unaccompanied by the prismatic colours. [ACHROMATISM; OBJECT-GLASS.]

The difference between the indices of refraction of the extreme rays of the spectrum formed by a prism of any substance is called the *coefficient of dispersion* with respect to that substance, or simply the *dispersion*; and the *dispersive power* is the quotient which is obtained by dividing the coefficient of dispersion by the mean index of refraction diminished by unity. The *mean index* is that of the ray which corresponds to the middle of the spectrum. As these terms are of frequent occurrence in scientific works, we shall illustrate the definitions by an example. According to Sir D. Brewster, the index of refraction of diamond for the extreme violet ray is 2.467, and for the extreme red ray 2.411; the difference of these two indices is .056, which, therefore, is the coefficient of dispersion for diamond. Again, the mean index, or mean of the above two numbers, is 2.439, which diminished by unity becomes 1.439; therefore the dispersive power of diamond is .056 divided by 1.439, or .0388. [REFRACTION; LIGHT; OPTICS; SPECTRUM.]

Displacement of a Vessel. The weight of water which a vessel displaces, which is of course equal to her own weight; the shipwright's or government measurement ought to furnish a very good approximation to the quantity thus ascertained, but they both are made to comprehend so many extraneous conditions that they afford very slight indications of the actual displacement.

Disposition. In Architecture, one of the six essentials of the art. It is the arrangement of the whole design by means of the ichnography (plan), orthography (section and elevation), and scenography (perspective view); and dif-

DISSECTION

fers from *distribution*, which signifies the particular arrangements of the internal parts of a building.

Dissection (Lat. *disseco, I cut asunder*). The cutting to pieces of any organised body with a view to elucidate its structure and functions. [ANATOMY.]

Disseisin. In Law, a species of wrongful ouster or putting out of him who is seized of the freehold in lands: it is either *single disseisin*, or *disseisin by force*, more properly termed *deforcement*.

Dissenters. Persons who dissent from the doctrines or usages of the established church of England. Roman Catholics, however, are generally referred to as a distinct class, and the term Dissenters applied to Protestants only.

The first dissenters from the church of England were the Puritans, who, at the beginning of the reign of Elizabeth, complained of the use of the surplice, the sign of the cross in baptism, and some other relics, as they esteemed them, of popery. The laws of Elizabeth, however, required their attendance at church under severe penalties; and no opportunity was allowed them, even though they held episcopacy itself in abhorrence, of forming separate sects or congregations. Perhaps the first distinct sect of Dissenters were the Brownists, who adopted very extreme opinions on the subject of church government, and against whom the punishment of death was enacted, as denying the queen's supremacy in ecclesiastical matters. On the accession of James I. an attempt was made by the puritanical party within the church to obtain a relaxation in some points of doctrine and discipline; but the conference at Hampton Court, which was convened upon that occasion, separated without effecting more than a few trifling alterations in the services. The penal laws continued in force, and Dissenters were not recognised as a distinct body by the state. They may be said to owe their origin in this sense to the assembly of divines convened by authority of parliament at Westminster in 1643, when a body of 120 clergymen and 30 laymen met and established the Presbyterian forms of doctrine and government, as set forth in the book called the *Directory*. The Independent party did not entirely accede to this settlement, and created some disturbances during the Protectorate. At the Restoration, the Presbyterian clergy were ejected on St. Bartholomew's day, 1662, by the Act of Uniformity, which re-established the Liturgy, and was attended with some circumstances of aggravation and harshness. Two thousand nonconforming clergy were thereby ejected from their benefices. The Corporation Act, requiring attendance on the sacrament preparatory to accepting municipal offices, was also passed at the beginning of this reign; and the Test Act followed, which excluded Dissenters in like manner from all places of trust and profit under government. These laws were repealed by 9 Geo. IV.; and Dissenters are now required only to make a declaration, according to the form of the Act, that

DISTEMPER

they will not exercise any influence they may possess by virtue of such office to injure or weaken the church by law established. The Act of Toleration (1 Wm. & Mary) had long since abrogated the penal laws of Elizabeth against Dissenters, excepting Papists and such as deny the Trinity.

Dissepiments (Lat. *dissepimentum*). In Botany, the partitions that are formed in the ovary by the united sides of the cohering carpels, and which separate the inside into cells; also called *septa*.

Dissidents. In modern European History, a term applied in Poland to those dissenters from the established religion (Catholic) who, under the old republic, were allowed the free exercise of their faith; including Lutherans, Calvinists, and Greeks, but excluding various minor sects. Their rights were fixed by the Religious Peace (*pax dissidentium*) of 1673, but they were infringed upon in the eighteenth century by various princes. They were supported in demanding the repeal of these restrictions by Russia and Prussia (in 1766), and hence those powers acquired one of their favourite pretexts for interference in the affairs of the Polish nation. Their rights were restored in 1775, with some exceptions; but after the Russian conquest they were placed on the same footing with the Catholics.

Dissolving Views. These popular phantasmagorical representations are produced by means of two magic lanterns [MAGIC LANTERN], which are placed side by side with their lens tubes slightly convergent, so that the projected images may be superposed upon the screen placed to receive them. An opaque rectangular shutter, capable of revolving vertically upon a pivot fixed midway between the two lanterns, is placed in front of the lenses in such a position that, when horizontal, it cuts off one half of the pencil of light from both lenses. If this shutter be made to revolve through a small arc, it must obviously shut off the whole of the pencil of light from one of the lanterns which we will call A, whilst it allows that from the other lantern B to pass unhindered. When the shutter is in this position, and each lantern is supplied with its slide, the image from B will be seen upon the screen in full brilliancy; but if the shutter be now made slowly to revolve in the opposite direction, the image from A will be gradually disclosed and that from B in the same degree concealed; the one appearing to dissolve whilst the other develops. To obtain a good effect with this apparatus, it is necessary that the lanterns should be illuminated with the lime light.

Dissonance. In Music, the same as *discord*.

Distemper. A disease of the dog. The _____ is commonly considered as a _____, and in general a running from the nose and eyes is one of the first and leading symptoms; it is usually accompanied by a short dry cough, and succeeded by wasting of the flesh and loss of strength and spirits.

DISTEMPER

The nasal defluxion, which is at first watery, becomes after some days, or perhaps weeks, mucous and purulent, loading the eyes and obstructing the nostrils; the cough becomes more distressing, and is attended by an effort compounded of coughing and vomiting; the listlessness, wasting, and loss of appetite also increase.

If the disease be virulent, symptoms of affection of the brain are its frequent concomitants, attended by fits, and great debility and paralysis of the extremities, or by convulsive twitchings resembling St. Vitus's dance; and such is the induced irritability of the animal at this period, that an angry menace or the sight of another dog will often bring a fit on, while fondling and encouraging a dog under these primary attacks will shorten their duration or altogether check them. If they continue, and increase in violence and frequency, they commonly prove fatal. 'If the fits,' says Mr. Blaine, 'have gained their full hold on the dog, a partial or total mental alienation takes place; when total, the poor animal is often perfectly phrenitic; he waters and dungs unconsciously; he tears up the ground, bites everything around him, and not unfrequently himself also. When the fit is over, he shakes himself, and looks and acts as usual, unless the attacks have been very violent and long-continued, when they leave him greatly exhausted and dispirited.' In some of these attacks the dog walks round and round, unconscious of everything about him. In such cases, the unfortunate animal is often supposed to be mad, and is frequently sacrificed accordingly; 'but the suddenness of the seizure ought to inform the looker-on of the total impossibility of its being *rabies*, which is always in the worst cases marked with some recollection, some knowledge, and which never exhibits the indiscriminate fury which characterises epilepsy.'

Inflammation of the lungs is by no means an unfrequent consequence of distemper; and the bowels are always more or less affected by diarrhoea and dysenteric discharges, often indicating ulceration of the intestinal canal, and accompanied by bloody mucus and extremely offensive evacuations.

Protracted cases of distemper are sometimes attended by a pustular eruption on the abdomen and chest, accompanied sometimes by an hepatic affection, called by sportsmen the *yellow disease*, from its giving the whole surface of the body a yellow hue: these are almost-always fatal symptoms.

The danger and fatality of this disease depend upon so many causes, that it is extremely difficult to prognosticate the results: it is frequently fatal to weakly and delicate dogs, and more so in town than in the country. Early in the disease a single fit is not alarming; but one or more fits in the advanced stages are seldom followed by recovery: impatience of light, red eyes, pneumonic attacks, and obstinate diarrhoea, are all bad symptoms; and spasmodic twitchings, a yellow tinge of the skin, and a

DISTICHIASIS

pustular eruption, are in almost all cases the forerunners of death.

Laxatives, emetics, and occasional bleeding, are the leading remedies in the early stage of this disease; obstinate diarrhoea should be checked by astringents; and warm bathing and antispasmodics must be resorted to to quell the violence of the fits.

The distemper is communicated by the contact of the diseased catarrhal secretion, and it may also be given by its inoculation; inoculation has indeed been proposed as a mitigation of the disorder, and it has been asserted that vaccination is a preventive. But it has been proved by Mr. Blaine that vaccination is quite inefficacious; and that inoculation with the matter of distemper is equally inefficient in mitigating the complaint, even when it is borrowed from the mildest forms. Many dogs, indeed, which have taken the disease by inoculation have had it with peculiar severity, and several have sunk under it. (Blaine's *Canine Pathology*.)

DISTEMPER or DASTEMPER (Fr. *détrempe*, Ital. *tempera*). In Painting, a preparation of opaque colour ground up with size and water, with gum-water, or similar vehicles. It is used especially in scene painting. This species of painting is also called, when practised on a small scale, *body-colour painting*, *tempera*, and *gouache*, from the Italian *guazzo*. Distemper or *tempera* was the ordinary method of painting in the higher departments of art, as well as illuminating, before the establishment of oil or varnish painting; many remarkable specimens of early Italian, Flemish, and German pictures of this class are in the National Gallery. The method is generally objectionable, the rapidity with which the vehicle dries rendering it difficult to blend the tints. This objection was in a great measure obviated by the Cologne and early English painters, by mixing a small quantity of honey with their *tempera*, which rendered it less drying. Egg and fig-sap have also been similarly employed: both were used by the ancients. But this method of painting has been generally superseded in Europe, for higher art, by the method of varnish painting established by the Van Eycks early in the fifteenth century. (*Eastlake's Materials for a History of Oil Painting*, 1847.)

[**OIL PAINTING**.]

DISTHENE (Gr. *δίσ*, and *σθένος*, strength). A name given by Hatty to Kyanite, in consequence of its double electric powers; some crystals becoming negatively, and others positively electric by friction.

DISTICH (Gr. *δίσχιος*). A couplet of verses. In the Greek, Latin, and German languages, this term is applied to pieces of poetry consisting of two lines, in hexameter and pentameter verse.

STICHIASIS (Gr. *δίσ*, and *σχιος*, a row). A double row of eyelashes, the innermost of which excite a constant irritation of the eye. The term *trichiasis* is generally applied to this malformation.

DISTICHOUS

Distichous (Gr. *dioryxos*). In Botany, term applied to the arrangement of organs in two rows, the one opposite to the other, as the florets of many grasses.

Distillation (Lat. *distillatio*). The evaporation and subsequent condensation of liquids by means of a *still* and *refrigeratory*, or of *retort* and *receiver*.

The discovery of the art of distillation is generally ascribed to the alchemists; but it was doubtless known in more remote ages to the Arabians, and by them probably derived from nations farther east.

The process of distillation, though in continual use in the chemical and pharmaceutical laboratory, is carried on upon the most extensive scale for the production of ardent spirits in the *distilleries*. Under the words ALCOHOL, BRANDY, FERMENTATION, WINE, &c. will be found some details bearing upon the nature, sources, and production of spirituous liquors; in the present article, therefore, we shall limit ourselves to an outline of the different processes which are more exclusively conducted in the British distillery.

There are two distinct operations in the production of ardent spirits: the one is the conversion of certain vegetable principles into alcohol; and the other, the separation of the alcohol from the other substances with which it is necessarily blended during its production.

The vegetable principle which is essential to the formation of alcohol is *sugar*; and this is sometimes used *directly*, as where molasses and analogous saccharine products are subjected to immediate fermentation; or it is *indirectly* obtained by subjecting amylaceous grains to certain processes, by which the starch they contain is first converted into sugar, and then that sugar afterwards alcoholised.

In our distilleries the latter alternative is adopted; and various kinds of grain, but chiefly barley, wheat, and rye, with more or less malt, are subjected to the operation of *mashing*. For this purpose the ground grain and the bruised malt are duly mixed, and infused under constant agitation in a proper quantity of hot water in the *mash-tun*; the wort is then run off, and fresh water added, till the soluble materials of the grain are extracted.

In this way the mixed worts or *wash* is obtained, which is afterwards to be subjected to fermentation; but in the distillery the operator is not, as in the brewery, left to his own judgment or convenience, but enforced to conform to the excise laws, which are of a very peremptory character. By these laws the distiller is restricted in the density of his worts to specific gravities between 1050 and 1090; and in Scotland, between 1030 and 1075. It is presumed that at those specific gravities, which are called 50 and 90, and 30 and 75, the actual quantity of saccharine or saccharifiable matter contained in each barrel (or 36 imperial gallons) amounts respectively to from 47½ lbs. to 85 lbs., and from 28 lbs. to 79½ lbs. When this wash is adjusted as to

DISTILLATION

density, it is run into the fermenting vats, where, mixed with a small quantity of yeast, it is subjected to the process of fermentation, which continues from six to ten or twelve days, the time required for its completion varying with the mass of liquid and with the temperature of the atmosphere.

During mashing, the starch passes into sugar, and during fermentation the sugar changes into alcohol; the consequence of which is that the wash gradually decreases in density or *attenuates*; and as soon as this attenuation has reached its maximum, which may be determined by the hydrometer, it should be distilled in order to prevent the commencement of acetic fermentation.

In all large distilleries there are two sets of stills: one for the purpose of distilling from the wash a weak spirit, technically called *low wines*; and the other for redistilling (or *rectifying*) the low wines. In these distillations there passes over along with the first and last portions of the spirits a peculiar volatile oil of a disagreeable flavour and odour, and rendering the weaker spirit milky. These portions are called *faints*, and are carefully turned into separate receivers as soon as the appearance of the runnings from the worm end indicates their presence.

The stills now universally employed are those invented by Mr. Eneas Coffey of Dublin. In this apparatus, technically known as *Coffey's still*, the spirituous vapour is condensed by the cold wash, which is thus gradually heated nearly to its boiling point, saving thereby a large amount of fuel. These stills can produce as much as 3,000 gallons per hour.

The quantity of alcohol which may be obtained from a given quantity of sugar will depend upon the skill and care with which mashing, fermentation, and distillation have been respectively conducted; theoretically, 100 pounds of sugar are convertible into about 61 of alcohol and 49 of carbonic acid. The quantity of alcohol to be procured from different kinds of grain will also depend upon the same causes, and upon the quantity of sugar, and of starch and gum convertible into sugar, which each may contain. According to Hermstedt, 100 pounds of starch should yield 36 pounds of real alcohol; and 100 pounds of the following grains should yield the following quantities of spirit of the specific gravity of 0.9427; that is, of spirit containing 45 per cent. of real alcohol; namely, wheat 40 to 45 pounds, rye 36 to 42, barley 40, oats 36, buckwheat 40, maize 40.

Sometimes, though rarely, malt only is used in the distillery, in which case the distiller calculates on obtaining two gallons of whisky of proof strength from each bushel of malt.

The *proof spirit* of commerce, and that of the Pharmacopœia, is generally stated to be of the specific gravity of 0.920 at 62°, and is considered as a mixture of *equal weights of absolute alcohol of the specific gravity of 0.791 at 60°, and of water*. The *rectified spirit* of commerce, or rather that of the Pharmacopœia, is directed

DISTOMA

to be of the specific gravity of 0.838 at 60°, and may be regarded as a mixture of about 82 parts of absolute alcohol and 18 of water. [SEINFUS.]

Distoma (Gr. *διστόμος*, double-mouthed). The name of a genus of Trematode intestinal worms, including those which have two suckers or organs of adhesion, of which the anterior alone is a true mouth; and the posterior or larger disc is situated on the ventral aspect of the body, a little way behind the mouth.

Distortion (Lat. *distortio*). An unnatural deviation of shape or position of any part of the body, producing visible deformity.

Some distortions are exclusively dependent upon disordered actions of the muscles or nerves, or both; certain kinds of lameness, for instance, arise from a want of due sympathy between the flexor and extensor muscles, or from an unnatural contraction of one or more muscles in consequence of the inefficiency of their opponents; hence various paralytic distortions, squinting, wry neck, and some forms of what is termed *club-foot*.

The most common cause of distortion, however, is disease of the bones, which, being sometimes deficient in their hardening or earthy principle, are incapable of supporting the weight of parts which they are designed to bear, or of sustaining pressure or muscular action, without more or less flexure. Of this kind is the disease called *rickets*, in which it has been presumed, though erroneously, that the vertebrae are the chief seat of the mischief. Besides rickets, there are other cases of curvature of the spine, the causes of which are by no means very obvious, more especially those of the *serpentine* or *lateral* curvature, which is not unfrequently among delicate girls in the higher and middling classes of life, though of very rare occurrence among the lower orders. This disease is usually observed about the ninth or tenth year, and the symptoms are generally traced in the following order: 1. The child makes frequent attempts to prevent the dress falling off one shoulder; 2. One shoulder appears higher than the other; 3. One of the collar-bones, or one side of the breast-bone, appears fuller than the other; 4. One hip appears to project; 5. One leg appears shorter than the other; 6. There is a peculiarity in the manner of walking, one foot being swung round and the shoulder thrown forward. When the girl reaches the age of twelve or thirteen (for this disease is *very rare* in boys), she becomes evidently twisted, and the spine is found to have assumed a serpentine form. In reference to the treatment of this kind of distortion, it appears that very opposite methods have been successful; thus, some patients have been confined for months to the same position; another violently exercised; another shampooed and acupunctured; a fourth relies on artificial supports, such as stays and bandages; a fifth is leeches or blistered; and many are told to attend only to the general health. The truth is, that distortion may depend upon different causes, and different remedies may be required in its different stages

DISTORTION

of progress. The serpentine curvature of the spine generally originates in muscular debility; and therefore, at its commencement, is appropriately treated by attention to the general health, by proper exercises and tonics. As the disease, however, proceeds, the muscles and ligaments acquire a certain form, and then artificial supports may be appropriately resorted to. In a yet more advanced stage, the vertebrae themselves become altered in form; and hence the spine may require to be stretched, and kept so during a considerable part of the twenty-four hours, so as to allow the bones to resume their natural form. When the ribs and sternum have become much displaced and misshapen, methods of compressing and remodelling them must be adopted; and lastly, when what is called *anchylosis*, or permanent bony deformity, has taken place, palliations and preventives of further mischief can alone be resorted to.

In all cases where there is a tendency to distortion, its early progress should be watched with the utmost solicitude, and *preventive means* steadily and perseveringly adopted. When a girl is eight or ten years old, she should not be confined to the schoolroom, and to a walk once or twice a day, but she should be induced by amusing and romping games to use active exercise, and especially such as brings the muscles of the trunk into play; she should not be kept long at the pianoforte, and her chair should be made so as to support her. If she has a tendency to lean to one side, she should be allowed to learn her lessons in a recumbent posture, and not constantly admonished to 'hold herself up.' By attention to these simple rules at a very early period of this tendency to distortion, its farther progress may be possibly prevented; but if the girl becomes listless, lounging, pallid, and awkward in her gait, the spine is probably becoming distorted; and in this case she should not be allowed to sit erect without using some artificial support, such as an arm-chair, or chair crutch, and she should read always lying down; while by the help of proper stays and a belt support should be given to the loins, the upper part of the chest being left free. No shoulder-straps, collars, or back-boards should be used to push in the projecting shoulder, unless the loins be at the same time supported; for in the majority of cases a sinking of the lumbar part is the cause of the inequality of the shoulders. The child should, in this stage of the disorder, be a good deal in the open air; not walking sedately, but, if possible, skipping about; and when she comes in, should not lounge on a chair, but lie down; or if out-of-door exercise be inadmissible, she should play at battledore and shuttlecock, and use a skipping rope. But whatever exercise be used, it should never be carried to fatigue. The child should sleep on a firm hair mattress, with scarcely any pillow; she should have good nourishing diet; occasional warm aperients and alkaline tonics may be proper, with cold bathing or sponging. By scrupulously following up the preceding plan,

DISTRRACTILE

the general health is improved, and the tendency to distortion often diminished; but constant care for months, and even years, can alone insure its removal. Where the spine has acquired a decided twist, a variety of mechanical contrivances, and many different plans of treatment, have been proposed and used with more or less success.

There is another kind of distortion, differing entirely from the preceding; namely, *angular curvature* of the spine. It generally proceeds from scrofulous ulceration of the bodies of the vertebrae; it is attended with paralysis of the lower extremities, and is often fatal. Similar disease often occurs in the other bones and joints of the body.

There are a variety of deformities resulting from other causes than those above adverted to; namely, from gout, rheumatism, and various chronic and local affections, which, however, do not come under the general term of *distortions*: nor can we properly refer to this head a variety of real deformities which are chiefly the consequence of dress and fashion; such as those which result from wearing stays, bandages, ill-made and tight shoes, and the like.

Distractile (Lat. *distraho, I draw apart*). In Botany, a term invented by Richard to denote a connective which divides into two unequal portions, one of which supports a cell and the other not, as in *Salvia*.

Distress. In Law, the taking of a personal chattel out of the possession of a wrongdoer into the custody of the party injured, to procure satisfaction for the wrong committed.

Distress may be had for various kinds of injuries, and as a means of enforcing process, or the performance of certain acts in various cases. But the most usual injury for which a distress may be taken is that of non-payment of rent. Distress for rent is said to be incident to the reversion; so that it may be taken for rent reserved upon a gift in tail, lease for life, years, &c., though there be no clause of distress in the deed, if the reversion is in the party distraining. It cannot, however, be taken for arrears of rent older than six years (3 & 4 Wm. IV. c. 27). Distresses are to be of things valuable, wherein some one has a property. But various species of personal chattels are exempt from distress, especially the utensils and instruments of a person's trade and profession, if in actual use; otherwise they are not privileged. *Excessive* distress, that is, unreasonably great, was rendered illegal as long ago as 52 Hen. III. by the statute of Marlbridge, which gave a special remedy to the sufferer. All distresses for rent must be made by day, and on the premises; but if any tenant fraudulently removes goods from off the premises, the landlord may within thirty days seize such goods wheresoever found, unless they are sold for a valuable consideration before the seizure. Persons who distrain for rent may sell the distress for payment of rent in arrear, if the tenant or owner fails to replevy, with sufficient security, within five days after taking the dis-

DISTRIBUTION

tress and giving the tenant notice of the cause. In this case the constable is bound to assist; the goods are to be appraised by two sworn appraisers; and the overplus, if any, left in the constable's hand for the use of the owner.

Distribution. In Political Economy, this term is used in two senses. In the former, it denotes the act by which the larger transactions of production and carriage are supplemented by the operation of certain agents, who bring commodities, by small parcels, within reach of the consumer's demand. In the growth of society, and in the freedom which economical science indicates as furnishing the best means by which individuals may employ their several faculties and opportunities for their own advantage, the tendency is always towards multiplying as far as is necessary all such intermediaries; the division of such occupations, just as in other kinds of labour, being determined by the 'width of the market.' In other words, when societies are large, there is always a disposition towards a separation of employments; caused by the fact, that larger profit to the individual, and by implication greater benefit to mankind, comes from undivided attention to one particular calling. In small societies, on the other hand, the same person undertakes to meet a multitude of wants, and can, therefore, offer neither the same intelligence in procuring nor the same variety in supplying as are achieved by the division of occupation. If all action be free, the number of persons intermediate to production and consumption is governed solely by the general advantage of society. This sense of distribution depends on reciprocity of services.

The other sense of *distribution* refers to the division of products. The gross amount of all labour is divided among the community; each individual, if a fair apportionment based on services rendered is effected, receiving his just share of the whole quantity. One man supplies muscular labour, another capital, a third supervision, a fourth protective, administrative, legal or military, a fifth education, and so on. In proportion to his contribution to the value of the produce, each receives, or should receive, his portion of the whole, the laws of society tending generally towards a just appraisal of the service rendered, by the operation of competition, of supply and demand, and of individual values.

This view of the term *distribution* is fundamental, and of the greatest significance in Political Economy. It must be understood in order to apprehend and interpret the bearings of the economical principles of Population, Law, and Taxation.

1. It is connected with theories of Population, because when population is in excess, or, in other words, when the supply of labour exceeds the demand, or the employment for it, the amount distributed to each individual from the fund of capital destined for wages is, in degree, less; and, on the other hand, when the supply of labour is scanty, the amount

DISTRIBUTION

received in wages is, conversely, more. It will be impossible that more should be given than the gross amount receivable by labour; and hence any attempt to regulate the wages of labour with a view to increasing the amount, will end in a mere diversion of part of the wages which one labourer should receive into the hands of another. [POPULATION; TRADES UNIONS.] Similarly, if profit is to be derived from capital, it will be impossible to lower wages when labour is insufficient for demand.

2. It is connected with Law, in so far as law determines the possession of land, or attempts to regulate price. In this country, where the rule of primogeniture prevails, and the privilege of strict settlement—that is, the power of continually creating a contingent estate in favour of non-existent persons—is permitted, the question as to whether such a system is beneficial or mischievous is constantly agitated. Hence it is that most English treatises on Political Economy are largely occupied with dissertations on rent, on forms of tenancy, and on the comparative advantages of the ordinary farming system and of actual ownership. Although, of course, the real question at the bottom of all disquisitions on the prevailing tenure of land in countries is political, and therefore wholly alien from any scientific consideration, the subordinate question of its economical effect is the legitimate province of the economist. [RENT; PRASANT PROPRIETOR; METATHE; RYOT.]

Legislatures have at all times attempted to regulate prices. It seems so natural to think that authority can decide tastes, or check habits, or give advantages, or secure a form of policy, and the countervailing forces to such enactments are, for obvious reasons, so obscure, that it is not wonderful that legislative action should have been invoked to confirm such supposed benefits. The attempts have always been failures. It is impossible to coerce natural laws. If legislative regulations are unwise, and can be evaded, they are evaded; if they are unwise, and cannot be evaded, they invariably inflict first a loss on the public, next a loss on the favoured object. If they are wise, they are as superfluous and supererogatory as it would be to pass a law in order to give effect to the solar system. [PROTECTION.]

3. It is connected with Taxation in so far as the incidence of taxation is just. Every man derives, or should derive, advantage from the administration of government, and should contribute proportionately, in consideration not only of the service which he receives from the public, but of that which he renders to the public. Hence the question of what he receives is of the greatest meaning in finance, if indeed finance is to be anything more than a raid on the weak and unprotected; and, of course, as money is only the measure of value, and the only true values are mutual services, it follows that each man's proportion is not what he takes in money, but what he gets in money's worth. Hence if we could prove sta-

DITRIGLYPH

tistically that the income of labourers (in the popular sense) receiving 100*l.* a year and the income of all above this condition were equal, and both incomes were taxed at equal rates, it would still be a question whether the purchasing power of the former is equal to that of the latter, and therefore whether the distribution of taxation is just. [MONEY; TAXATION.]

DISTRIBUTION. In Printing, the replacing of the types in their respective boxes in the cases, after being printed off, preparatory to their being set up again. [COMPOSITION.] A handful of the types is wetted, and held in the left hand. The types are then thrown letter by letter into the case with the forefinger and thumb of the right. The freedom from error in proofs depends mainly on *clean* distribution.

District (Lat. *districtus*, part. of *distingo, I sunder*). A territorial division. This term was formerly used in France, and particularly in the year 1790, when, by the law of February 16, the whole country was divided into 565 districts; and it is still common to many of the Continental states. The county of Lincoln is divided into three districts: Lindsey, Kesteven, and Holland. These divisions are of great antiquity, and in all probability owe their origin to the distinct natural features by which they are characterised.

Distringas. In Law, a writ addressed to the sheriff commanding him to distrain goods [DISTRRESS] in several cases, of which the most usual was formerly to compel an appearance. It is now abolished by the amendment of process (1852). In Equity, a *distringas* is issued to compel appearance by a corporation aggregate; and it is also issued for the purpose of preventing the transfer of stock or payment of dividends by the bank of England, at the suit of a party claiming to be interested therein, under 5 Vict. c. 6.

Ditch or Fosse. In Fortification, the excavation round the work, serving as an obstacle to the enemy, and supplying earth for the parapet.

Dithionie Acid (Gr. *dis*, and *thion*, sulphur). Berzelius applies this term to the *hyposulphuric acid*; and he calls the sulphurous acid, *dithionous*. The term implies the existence of two atoms of sulphur in each of these acids.

Dithyrambic Ode (Gr. *διδυμικός*). A species of Greek lyrical poem in honour of Bacchus, which derived its name from Dithyrambus (*Διδυμικός*), one of the appellations of that deity: a word of uncertain meaning and etymology. The style of this poetry was very bold, often passing into bombast; so much so indeed as to become proverbial for the latter quality. In modern times the term is indiscriminately employed to designate odes of an impetuous and irregular character. [ODD.]

Ditone (Gr. *δίτονος*). In Music, an interval consisting of two tones.

Ditrigrlyph. In Architecture, an arrangement of the intercolumniations in the Doric order, by which two triglyphs are obtained in

the frieze between the triglyphs that stand over the columns.

Ditto (Ital. *detto*, *the said*). In Book-keeping, more usually contracted into *Do*, signifies the same as that which precedes it.

Diuresis (Gr. *diúrōis*, *a discharge of urine*). An excessive flow of urine. [DIABETES.]

Diuretic. This term signifies literally anything which increases the secretion of urine. It is usually applied to certain medicines which act specially upon the kidneys, such as squills, turpentine, and some of the neutral salts; and it frequently happens that during an inordinate flow of urine derived from such causes watery fluids are absorbed from other parts, and, as it were, transposed to the kidneys: upon this principle is founded the use of diuretics in dropsy. There are some alteratives which operate as diuretics, especially when they are taking a favourable operation upon the system: this seems especially to be the case with sarsaparilla. Water and other diluents and liquids, when taken in excess, also operate as diuretics; as far, at least, as mere increase in the flow of urine is concerned.

Diurnal (Lat. *diurnus*, from *dies*, *a day*). The name given to the book containing those canonical hours of the Roman Catholic breviary which are to be said during the day. It is intended especially for the clergy of the Roman church, and consists generally of four volumes, one for each season of the year.

Diurnals (Lat. *diurnus*). A tribe of Rap-torial birds, including those which fly by day and have lateral eyes: also a family of Lepidopterous insects, which have a similar period of activity.

Divan. A word common to many of the Eastern languages, signifying in Turkish the audience-chamber of the vizier, or supreme judicial tribunal. The divan of the caliphs was a court for the relief of petitioners, over which those monarchs presided in person. The Turkish divan, as is well known, is the great council of the empire.

It would seem that the earliest acceptance in which this word was employed is that of a muster-roll or military day-book; and we find it used, especially by the ancient Arabs, who borrowed it from the Persians, to signify a collection of poems by one and the same author, arranged in alphabetical order; thus we hear of the Divan (i. e. the collected poems) of Sadi, the Divan of Hafiz, &c. The word *divan* is also among the Turks a common appellation for a saloon or hall which serves for the reception of company, for the transacting of business, or for occasional repose; hence in common the use of the term to signify a sofa.

Divaricate (Lat. *divarico*, *I stretch asunder*). In Botany, spreading abruptly at an obtuse angle.

DIVARICATE. In Zoology, when the divisions of a part spread out widely.

Divergent (Lat. *dis*, and *vergo*, *I incline*). In Zoology, when the branches form a right

angle with the stem; as the snags of certain antlers, the divisions of certain Polyptarises, &c. **Divergent Series**. [CONVERGENT AND DIVERGENT SERIES.]

Diverging. In Botany, used in describing the venation of leaves, to denote the angle which is formed by the midrib and one of the primary veins, when it is between 20° and 40°.

Dividend (Lat. *dividendus*, *to be divided*). In Arithmetic, the number or quantity given to be divided. Dividend, in Commerce, is the name given to the payment made to creditors out of the estate of a bankrupt, and to the annual interest payable upon the national debt and other public funds.

Divination (Lat. *divinatio*). The art of foretelling future events. At an early time divination formed a regular science, intimately allied to religion, and furnished with rules and regulations. Of all the nations of antiquity, few cultivated the science of divination with such enthusiasm as the Greeks and Romans. Under the different heads, as *HELOMANCY*, *NECROMANCY*, &c., the reader will find a notice of the principal methods of divination; and for the rest he may consult with advantage Cicero *De Divinatione*. [ORACLE.]

Divine Right of Kings, the. In Politics, means the absolute and unqualified claim of sovereigns on the obedience of the people; inasmuch that, although they may themselves submit to restrictions on their authority, yet subjects endeavouring to enforce those restrictions by resistance to their unlawful acts are guilty of a sin. This doctrine, so celebrated in English constitutional history, has been asserted on very different grounds. Hobbes (*De Civ.*) deduced the absolute authority of kings from the supposed social contract, whereby men parted absolutely with their natural rights in exchange for protection. But the fashionable political writers and theologians of the times both of Charles I. and Charles II. (in the latter reign, Sir Robert Filmer, author of the *Patriarcha*, may be more especially cited, on account of his having been directly answered by Leslie) maintained that government had an existence before property, and before any supposed social contract could take place; that it originated in the patriarchal sway, which was succeeded by the regal, and that no other was authorised by Scripture. See also the *Convoocation Book* of 1603; Archbishop Leslie on the *Power of the Prince*; Sherlock's *Case of Resistance to Supreme Power*, 1684; Mackenzie's *Jus Regium*, 1682. The same principles were practically adopted by the Jacobites, when they maintained the divine right of the expelled sovereign, and afterwards of his descendants, by hereditary title. As to the views of modern high-church divines on the subject, see Dr. Pusey's *Sermon on the 5th of November*, 1837. [NON-RESISTANCE.]

Diving (another form of *dép*; Dutch, *duypen*). The art of descending in water. Independently of the valuable native productions which are found at the bottom of the sea, each

DIVING BELL

as pearls, coral, sponges, &c., the treasure which is so frequently carried down in wrecked vessels makes it an object of importance to be able to descend to the bottom and remain there long enough to execute the operations necessary to recover it. But without the assistance of some mechanical apparatus, even the most practised divers can do very little. A minute and a half, or two minutes, is the longest time that a diver, in general, can remain under water. Besides, on account of the loss of weight in water, the power which a man can exert is extremely small, unless borne down by a load which would entirely prevent him from rising again to the top.

The diving helmet and the diving bell [DIVING BELL] are the apparatus employed in operations requiring prolonged submersion.

The diving helmet is made of thin sheet copper, which covers the head of the diver, large enough to admit of free motion, and furnished with three eye-holes, covered with glass protected by brass wires. The helmet comes pretty well down over the breast and back, and is fastened by rivets to a waterproof canvas jacket so tightly that no water can penetrate. A leather belt passes round the diver, to which are attached two weights, one before and the other behind, each about 40 lbs. The belt is supplied with a buckle in front, which, in case of any accident happening, can be instantly undone. The diver is supplied with fresh air by means of a flexible waterproof pipe, which

enters the helmet, and communicates with an air-pump, worked above in the barge from which he descends. This pipe passes under the left arm of the diver, and enters the back of the helmet, being so contrived that the fresh air is made to impinge on the glasses; which in a great measure prevents their being dimmed by the moisture of the breath. From the back part of the helmet there is also led an eduction pipe, to allow the escape of the breathed air. A signal line passes under the right arm to communicate with attendants at the surface. The diver descends from the side of the vessel, either by means of a rope or wooden ladder, loaded at the lower end, the weight being kept at a little height above the ground. When the diver descends to the bottom, the weight is let down, and the rope allowed to become slack, to prevent the motion of the boat from obstructing him. His motion is rendered steady by heavy weights attached to his feet; and he carries a line in his hand, that he may, when necessary, guide himself back to the rope. A waterproof dress covers his body entirely; and he is thus enabled to remain under water five or six hours at once, all the while perfectly dry.

Diving Bell. An apparatus by means of which persons are let down and enabled to remain under water, and execute various operations; such as levelling or clearing the bottoms

of harbours, preparing a foundation for buildings, bringing up sunken materials, &c. The principle of the diving bell depends on the impenetrability of atmospheric air, and may be illustrated by a very familiar experiment. Bring the edge of an inverted tumbler, or any close vessel, to the surface of water, and, keeping the mouth horizontal, press it down in the water. It will be seen that, though some portion of water ascends into the tumbler, the greater part of the space remains empty, or only filled with air; and any object placed in this space, though surrounded on all sides with water, would remain perfectly dry. In fact, the quantity of air remains the same, but is compressed into a smaller volume, in proportion to the depth to which it is made to descend. Now, if we conceive a vessel of wood or iron, sufficiently capacious to hold several men, to be suspended by a chain, and lowered by means of weights attached to it to any moderate depth under water, it is evident that they may remain there for a considerable time, and perform any operation that could be executed on land in the same confined space. The machine, however, as thus described, is liable to two great defects, which must be obviated by other contrivances before any great advantage can be derived from it. In the first place, as the air by its compressibility allows the water to enter the lower part of the bell, the dry space is not only diminished, but the bottom on which the bell rests, and where the operations are to be carried on, is also covered with water to a proportional depth. In the second place, the air within the bell by repeated respiration soon becomes impure, and unfit to support life; so that it is necessary to elevate the apparatus after short intervals, to admit a fresh supply.

These defects were remedied by Mr. Smeaton, who contrived the plan of forcing down a continued stream of air by means of an air-pump through a flexible tube; and this plan is now always adopted. In the year 1788 Mr. Smeaton constructed a diving bell, to be used in the operations then contemplated at Ramsgate harbour, on a new and improved plan. Instead of a bell-shaped vessel sunk by weights, his apparatus consisted of a square chest of cast iron, four and a half feet long, four and a half feet high, and three feet wide, affording sufficient room for two men under it. It was cast of such a thickness that its own weight was sufficient to sink it; and its thickness was greatest near the mouth or lower part, to prevent it from being easily overset. This construction of the diving bell gave the men within it no power of raising or sinking it; but as the apparatus was made to be used at a place where the nature of the bottom was known, this disadvantage was not considered of great consequence; and, in fact, it is found by experience that it is better to leave the bell to be entirely guided from above. On account of the facility with which water conveys sound, the strokes of a hammer on the inside of the bell can be heard at a great distance; and the

DIVINING ROD

sound coming through the water has a peculiar character, which cannot be mistaken. By previous arrangement, any directions can be given in this manner. For instance, one blow may denote *more air*; two, *stand fast*; three, *heave up*; four, *lower down*; and so on. With these successive improvements, the diving bell is found to be a most important machine in all great operations to be performed under water.

Divining Rod. [RHANDOMANCY.]

Divisibility. The property which all bodies possess of being separable into parts. It was a question formerly much agitated among philosophers whether matter is divisible *in infinitum*; or whether a certain term does not exist beyond which the particles are reduced to simple atoms incapable of further division. The question is incapable of direct solution, and fortunately is of no importance to science; but the extent to which the actual subdivision of bodies has been carried in many cases in the arts may well be considered as prodigious. 'In the gilding of buttons, 6 grains of gold, which is applied as an amalgam with mercury, is allowed to each gross; so that the coating left must amount to the 110,000th part of an inch in thickness. 'If a piece of ivory or white satin be immersed in a nitro-muriate solution of gold, and then exposed to a current of hydrogen gas, it will become covered with a surface of gold hardly exceeding in thickness the ten-millionth part of an inch.'

'The solution of certain saline bodies, and of other coloured substances, exhibits a prodigious subdivision and dissemination of matter. A single grain of the sulphate of copper, or blue vitriol, will communicate an azure tint to five gallons of water. In this case the copper must be attenuated at least ten million times; yet each drop of the liquid may contain so many coloured particles, distinguishable by our unassisted vision. Odours are capable of a still wider diffusion. A single grain of musk has been known to perfume a room for the space of twenty years. Animal matter likewise exhibits in many instances a wonderful subdivision. The milt of a cod-fish when it begins to putrefy has been computed to contain a billion of perfect insects, so that thousands of these living creatures could be lifted on the point of a needle. But the infusory animalcules display in their structure and functions the most transcendent attenuation of matter. The *Vibrio undula*, found in duck weed, is computed to be ten thousand million times smaller than a hemp seed. The *Vibrio lincola* occurs in vegetable infusions, every drop containing myriads of these oblong points. The *Monas gelatinosa*, discovered in ditch water, appears in the field of a microscope as a mere atom endued with life, millions of them playing like sunbeams in a single drop of liquid.' (Leslie's *Natural Philosophy*.)

Division (Lat. *divisio*). One of the four fundamental rules of Arithmetic, the object of which is to find how often one number is contained in another.

DIVORCE

The number to be divided is the *dividend*, the number which divides is the *divisor*, and the result of the division is the *quotient*. Division is an inverse procedure, whose effect is annulled by the *direct* operation of multiplication. Its character is *interrogative*, rather than *directive*. In order to discover the subject upon which the direct operation of multiplication will produce a given result, we must necessarily have recourse to guesses, suggested it is true by a previous knowledge of the direct operation, and test the accuracy of the procedure by multiplication. The study of the true nature of division is essential to a clear comprehension of the higher calculus of operations.

DIVISION. In Logic, the enumeration of several things signified by a common name; thus, tree is said to be divided into oak, ash, elm, &c. A common term may be divided in several ways, according to the various points of view in which it may be regarded for the purpose of qualification. Thus a bookbinder may divide books into folios, quartos, &c.; a librarian, into theological, historical, &c.

DIVISION. In the art Military, signifies: 1. Two or more brigades combined under a general officer [BURGADA]; 2. Two guns of a battery of artillery with their personnel and equipment [ARTILLERY]; 3. Any troops under a separate command forming part of a larger body.

DIVISION. In Music, a dividing or separation of the interval of an octave into a number of lesser intervals.

DIVISION. In Printing, dividing words according to custom and grammatical rule. Words of two syllables, where one of the syllables consists only of one letter, such as *brown-y*, *cloud-y*, &c., are never divided by printers. Wide spacing in one line and close in the next is bad work; and it is therefore advisable that words should be divided in such a way as to preserve uniformity of spacing as nearly as possible.

Divorce (Lat. *divortium*, *a separating*). The Jewish law of divorce is founded on the directions given in Deuteronomy xxiv.; but the permission therein contained is subject to many obstacles and formalities in modern practice. In ancient Greece, the practice of divorce seems to have varied in different states; at Sparta it appears to have been unusual, in Athens great facilities were afforded by the law. In republican Rome great strictness in this branch of morals prevailed for a long period, although parties were less impeded in pursuing a divorce by the difficulties imposed by the law than by public opinion. But in the later period of the republic, and under the emperors, divorce became extremely common, and was obtained with equal ease by either sex. The answer given by our Lord to the Pharisee (St. Matt. xix.) became the foundation of the law on this subject in Christian countries, and divorces were consequently allowed in the particular case of adultery only; but after the Romish church had erected matrimony into a sacrament, they

became, as they now are in Catholic countries, wholly impossible: the only dissolution of marriage being in cases where it is void ab initio. In most Protestant countries, the facility of divorce has been so much restored in latter times as to approximate to the heathen practice. As to the English law, see MARRIAGE, LAW OF.

Do. In Music, a syllable used by the Italians instead of *ut*, being considered more musical and resonant. It corresponds to the C of the English and Germans, but is sometimes used to denote the tonic or key-note of any scale.

Doberniner's Lamp. A small instrument for obtaining instantaneous light, in which a jet of hydrogen gas is inflamed by coming into contact with spongy platinum.

Doctes (Gr. *doctes*). One of the earliest heretical sects; so called from denying the reality of our Lord's incarnation, and considering Him to have acted and suffered only in appearance. Some have conceived that the declarations of the nature of Christ in St. John's writings were directed against these opinions.

Doctinastia. [DOXIMASIA.]

Doctinastic Art (Gr. *doctinastic*, *I prove*). The art of assaying minerals or ores, with the view of determining the quantity of metal which they contain.

Dock (Ger. *docke*). An artificial basin for the reception of ships. Docks are of several descriptions; either wet or dry, open or enclosed. The former are used for the purpose of loading or unloading a ship's cargo out of the influence of the tide, and are constructed with gates, which, when shut, keep the ship constantly afloat at low water. The second class of docks are intended for the building, repairing, and examination of ships, which are admitted into them at flood tide, and are so called because they are either left dry by the ebbing of the sea, or rendered so by the use of great flood-gates, or of pumps. The open docks are those which are, as their name implies, open to the public, such as the Liverpool and Havre docks; the enclosed ones are those where the circulation of the public is impeded by an enclosure wall, as in the London and Southampton docks, the Royal docks, &c.

Docket, Doequet or Doggett (Lat. *documentum*). In Law, an abridged entry of an instrument or proceeding on a small piece of paper or parchment. Exemplifications of decrees in chancery, flats in bankruptcy, and other instruments, are thus *docketed* for purposes of reference.

Dockyard, Naval. A place provided with all sorts of naval stores, timber, and all the requisite machinery for shipbuilding. The principal naval dockyards for the British navy are Portsmouth, Plymouth, Chatham, Sheerness, Woolwich, Pembroke, Cork, and Malta. Each dockyard is under the control of an admiral or captain-superintendent.

Doctor (Lat. *a teacher*). This title of learned distinction was first adopted in the twelfth

century. The degree of *doctorate*, and superior to that of *master* in European universities, was first conferred at Bologna; by the university of Paris, in 1146, on Peter Lombard; in England, it is supposed, in the reign of King John. Before this time, if the appellation *doctor* was used, it was only in its plain sense of teacher, and as synonymous with master. The degree of *doctor* is conferred, in the English universities, in each of the three faculties of divinity, law, and medicine—but not in that of arts—and in the science of music. The Continental degree of *doctor of philosophy* is unknown among us.

Docton. A thin plate of steel used in scraping the colour or mordant off the copper plates employed in calico printing; the term is probably a corruption of the word *abductor*.

Doctors' Commons. The popular name for the courts and offices occupied by the body incorporated in 1768 under the title of 'The College of Doctors of Law exercising in the Ecclesiastical and Admiralty Courts.' These courts are on the southern side of St. Paul's Churchyard. The college consists of a president (the Dean of the Arches for the time being), and of those doctors of law who having regularly taken that degree in either of the universities of Oxford or Cambridge, and having been admitted advocates in pursuance of the rescript of the archbishop of Canterbury, have been elected fellows of the college in the manner prescribed by the charter. But the practical functions of this body of lawyers have been very materially diminished, and the college has been empowered to sell its property and surrender its charter. (20 & 21 Vict. c. 77.) [COVERS.]

Doctrinaires (Fr.). In Politics, a cant word, originally applied in France to a section of politicians who occupied a place, in the first chambers after the restoration of 1816, between the deputies of the centre, who generally supported ministers, and the extreme left, which always opposed them. The chief men of this party were systematic writers and speakers on government, who sought to establish a frame of constitution somewhat more resembling that of England than any which has hitherto subsisted in France. The nickname given to them implied that they were considered by the public as theorists: they were, in fact, the same class which Napoleon used to term *Ideologists*. They supported the *duc de Cases* when in office; afterwards they were generally in opposition until 1830, since which time several of their leaders have held office at different times. Royer-Collard, De Broglie, the young baron de Staël, Guizot, &c., were among the chief public men commonly called *Doctrinaires*; but this, like other party nicknames, has been, and is, employed in a very arbitrary manner.

Documents (Lat. *documentum*). In Law, written instruments adduced for the purpose of evidence. [EVIDENCE.]

Dodder (Fris. *dodd*, *a bunch*; Dutch, *dot*, *hampered thread*). A family of curious leafless parasitical plants, the slender entangled thread-

DODECADACTYLUS

like, often reddish, stems of which run over and smother the plants to which they affix themselves. The genus is called *Cuscuta*, and the more familiar species are *C. europæa*, which attacks thistles, oats, and similar herbaceous plants; *C. Epithymum*, found on heath, furze, &c.; *C. Epilinum*, which attacks flax; and *C. Trifolii*, which is sometimes a grievous pest in clover-fields. [CUSCUTACEÆ.]

Dodecadactylus (Gr. δώδεκα, *twelve*, and δάκτυλος, *a finger*). The portion of the small intestines called *duodenum*, its length being about the breadth of twelve fingers: this at least may be the case in some animals to which the dissection of the earlier anatomists, who gave this name, was limited.

Dodecagon (Gr. δώδεκα, and γωνία, *angle*). An equilateral and equiangular figure of twelve sides. Approximately, the area of a dodecagon is 11·196 times that of the square on one of its sides.

Dodecahedron (Gr. δώδεκα, and ἔδρα, *a base*). One of the five Platonic bodies or regular solids. It has twelve equal pentagonal faces, thirty equal edges, and twenty equal solid angles, each formed by the meeting of three equal plane angles. Approximately, the superficial area of a dodecahedron is 20·6467 times that of the square, and its volume 7·66312 times that of the cube on one of its sides.

Dodecandrous (Gr. δώδεκα, and ἀντήρ, *a male*). Any plant having twelve stamens.

Dodecastyle (Gr. δώδεκα, and στύλος, *a pillar*). In Architecture, a building having twelve columns on a front, or on a flank.

Dodo. [DODU.]

Dodona, Oracle of. A celebrated oracle in Epeirus, sacred to Jupiter. In some legends its origin is attributed to Deucalion; according to the traditions of the priestesses of the temple, it was founded by a dove, which, perching on the branch of an oak, recommended in a human voice that a temple should be erected to Jupiter in that place. In the Homeric age this oracle was in Thessaly. (Homer, *Iliad* 16, 233; Gladstone's *Homer and the Homeric Age*, i. 106.) The legends of the foundation of the oracle are related by Herodotus, ii. 56, &c. [ORACLE.]

Dodrans (Lat.). A measure equal to about nine inches, being the space between the end of the thumb and of the little finger when both are fully extended. It is about equal to the *palm*.

Dodeglic Acid. An oily acid contained in some kinds of sperm oil.

Dog. [CANIS.]

Dog Belts. A term used in some coal mines for a strong broad piece of leather round the waist, to which a chain is attached, passing between the legs of the men drawing the duns in the low works.

Dog Days. [CANICULAR DAYS.]

Dog Rose. *Rosa canina*. Wild Brier. The fruit of this tree, called *hips*, is the source of a conserve, used in Pharmacy.

Dog Star. A name popularly given to *Sirius*, a star of the first magnitude, in the

DOGE

constellation *Canis major* (the Greater Dog) and the brightest fixed star in the firmament.

Dog's-leg Staircase. A staircase of wood in which there is no well hole, and in which the side strings of the half flight finish in the newel at the landings, or at the turn of the stairs.

Dog's-tooth Spar. A name given to certain pointed crystals of Calcespar, from their fancied resemblance to the tooth of a dog. They are principally found in Derbyshire, and at Ecton in Staffordshire.

Doge (from Lat. dux, *ducis*, *a leader*). The title of the supreme executive magistrate in the republic of Venice. The origin of this office dates as far back as 697; when, owing partly to the dissensions and intrigues that resulted from the annual election of the seven tribunes by whom the affairs of Venice had been previously administered, and partly to so divided an authority being found inadequate to the conduct of the rapidly increasing powers of the state, the Venetians resolved to replace the tribunes by a single chief magistrate, who should hold office for life. This magistrate, whom they called the *Doge*, was clothed with almost regal authority. In him was vested the power of convoking assemblies, of declaring war or concluding treaties; of commanding the armies of the state; of appointing the military tribunes and the judges; of hearing appeals and deciding definitively on all matters at issue; of collecting the citizens in the different quarters or districts of Venice, for the purpose of choosing their parish priests or bishops; of judging all matters concerning the clergy in all causes, both civil and criminal; and of awarding ecclesiastical punishments, investing the bishops, and installing them in their churches. (*And. Dandolo apud Galliccoli. Chron.* i.) But notwithstanding these apparently vast powers which were vested in the doge at the first institution of the office, the slightest glance at the history of Venice, which for more than eleven centuries, with a few interruptions, continued to be governed by doges, will abundantly prove that though the Venetians allowed four centuries to elapse before they attempted to fix the bounds or control the exercise of the sovereign authority by any legal enactments, they never ceased to regard with jealousy the chief magistrate of their own appointment and approval, and at last succeeded in limiting and restricting his power, so as to render him a mere state pageant of the grand council, in which resided the supreme executive authority. (*Daru's Histoire de la République de Venise*, 8 vols. 8vo. Paris; *Quarterly Review*, vol. xxxi.; *Edinburgh Review*, vol. xlv.) [BUCENTAUZ.] *Doge* was also the title given to the chief magistrates of Genoa, who were elected from the senatorial body. The doges of Genoa held office originally for life, as at Venice; but from 1528 down to 1797, when that form of government was abolished by the French, they remained in office only two years, and their authority was exceedingly circumscribed.

DOGGER

Dogger (Fr. *dogre*). A two-masted fishing boat, of the ketch build, with bluff bows. It is used principally by the Dutch for the Dogger-bank fishery. In the Dutch and Scandinavian languages the dogger is known as a *pink*.

Dogma (Gr. *a decree*). In Theology, *dogma* has been defined to be a fundamental article of belief derived from acknowledged authority, and is usually applied to what are considered the essential doctrines of Christianity, deduced either from the Scriptures or from the fathers of the church. [THEOLOGY.] There are, however, many other *dogmas* peculiar to the different sects into which Christianity is divided. *Dogmatic theology*, as this branch of divinity is called, in contradistinction to moral and scholastic theology, forms an important object of study in many of the Continental universities. In the Protestant universities of Germany, there are chairs set apart for the history of *dogmas*, or, as it is termed, *Dogmatik*: in which the origin and nature of the dogmas of the various Christian sects are examined, and the merit of the arguments by which they are supported respectively canvassed. Among the ancient physicians, the *dogmatists* founded their practice upon conclusions or opinions drawn from certain theoretical inferences, which they conceived might be logically defended or proved.

Dogwood. A name applied to various plants: in England and North America to the shrubby species of *Cornus*; in the West Indies to *Piscidia erythrina*; and in Tasmania, to *Befordia salicina*. Some of the North American species of *Cornus*, especially *C. florida*, are valuable trees. The *Piscidia* is a powerful narcotic, and is used as a fish-poison in Jamaica.

Dokimasia (Gr. from *δοκιμάζω, I prove*). In Greek Antiquities, the examination passed by Athenian magistrates before entering on their office. It embraced their past life generally, and their special fitness for the post for which they had been chosen; and any citizen might then object to the appointment. At the end of their term of office, they had to pass a second examination termed *Euthyne* (from Gr. *eûthynê, I set straight*). Except in offices involving the administration of public moneys, it was simply an appearance before the magistrates, when, if no charge was preferred against them, they were dismissed free of further obligation.

Dolabriform (Lat. *dolabra, an axe, and forma, form*). In Botany, applied to those bodies, principally leaves, which are fleshy, compressed towards the upper end, with one border thick and straight, the other thin and convex.

DOLABRIFORM. In Zoology, when a whole or part is shaped like a hatchet, as the foot of certain Bivalves.

Dolce (Ital.). In Music, an instruction to the performer that the music is to be executed softly and sweetly.

Dolerite. A trap-rock composed of augite and felspar.

DOLOMITIC CONGLOMERATE

Dolichocephalic (Gr. *δολιχός, long, and κεφαλή, head*). Professor Reubius used this word to denote those skulls in which the proportion of the transverse to the longitudinal diameter is less than $\frac{1}{10}$. The West African negro is an example of the dolichocephalic type of skull, to which the majority of the African races belong. No exact classification, however, can be formed upon the mere length and breadth of the skull, a character variable in nearly allied races.

Dolichos (Gr. *long*). A genus of *Leguminosæ* consisting of herbaceous or shrubby twiners with trifoliate leaves, the flowers succeeded by pods, which are sometimes esculent. *D. asquipedalis*, a native of South America, and cultivated in the warmer parts of Europe, has cylindrical pods a foot and a half long, which form an excellent dish when cooked young. The *D. tuberosus* of Martinique yields a fleshy tuber, as well as pulso, both of them edible; and *D. uniflorus* is grown for food in India under the name of Horse Grain. The *Dolichos pruriens* of Linneus is the *Mimuna pruriens* of De Candolle; it furnishes the article of the materia medica known as Cowitch. [COWHAGE.]

Dolichotis (Gr. *δολιχός, long, and οὖς, an ear*). The name applied by F. Cuvier to the subgenus of Cavies, to which the Patagonian hare (*Cavia Patagonica*) belongs.

Dollar. [MONET.]

Dolmen. Celtic monuments, consisting of two vertical stones and a horizontal one; they are usually erected in isolated positions, and are supposed to have served as altars.

Dolomite (after Dolomieu). In Geology. [PERMIAN AND MAGNESIAN LIMESTONE.]

DOLomite. In Mineralogy, a specific name for the rhombohedral compounds of carbonate of lime and magnesia. It includes the varieties Pearl Spar, Bitter Spar, Meisite Spar, and Breunnerite.

As a rock, the name is given to limestones containing carbonate of magnesia, those varieties that approach nearest in composition to equivalent combinations of the two carbonates yielding the most durable building-stones. In England, fossiliferous dolomites form the most part of the Permian Limestones from Durham to Nottinghamshire; and certain beds of the Carboniferous Limestone are, also, dolomitic. In the Tyrol, Canada, and other mountain districts, local masses of limestone are found to be changed into crystalline dolomites over extensive areas.

Dolomitic Conglomerate. Near Bristol and elsewhere, the unconformable beds of the lower new red sandstone, resting immediately on the coal, consist of a deposit known under this name. It is a breccia of fragments, often angular, composed of old rocks, chiefly carboniferous, cemented by a red or yellow paste of dolomite or magnesian limestone. This deposit contains fossil remains of some remarkable species of reptiles, for a long time regarded as the most ancient forms of reptilian life. Other

reptilian bones have since been found in the coal measures.

Dolphin (Gr. *δαλφίς*). This term is applied, in common language, to two inhabitants of the ocean of widely different habits and organisation: by naturalists it is generally used to signify the dolphin of the ancients, which is a cetaceous mammal of the genus *Delphis* of Linnaeus; by-poets it is applied to the coryphene (*Coryphæna Hippurus*, Linn.), a fish long celebrated for the swiftness of its swimming, and the brilliant and beautiful colours which it successively assumes in the act of death.

Dom (Lat. *dominus*, a lord). In the middle ages, a title originally possessed by the pope, and at a somewhat later period by the dignitaries of the Roman Catholic church. In more recent times, it formed a distinguishing title of certain monastic orders, such as the Benedictines, &c.; and it appears to have been equivalent to the *don* of the Spaniards, the *von* of the Germans, and the *de* of the French. Mabillon and Calmet are always spoken of as Dom Mabillon and Dom Calmet.

Domain (Lat. *dominium*, from *dominus*, lord; in legal language, *demesne*). Signifies properly that portion of the territorial possessions of a lord which he retains in his own occupation. Thus, the lands retained in possession of the crown, and not granted out to the great feudal lords, were styled *domaines* in France. *Ancient demesne*, in English law, is a peculiar tenure by which certain lands are held of the crown, being such as are evidenced by Domesday Book to have been in the possession of King Edward the Confessor.

Dome. In Architecture, the spherical, or other figured, concave ceiling, over a circular, or a polygonal, building; in the latter case, when the spherical shape is given, the dome is said to spring from pendentives, or the means of overcoming the difference of plan. A *surbased* or *diminished dome* is one that is segmental in its section; a *surmounted dome* is one that is higher than the radius of its base. The forms of domes are various both in plan and in section. In the former, they are circular or polygonal; in the latter we find them semicircular, semi-elliptical, segmental, pointed sometimes in curves of contrary flexure, sometimes bell, &c. The oldest dome on record is supposed to be that of the Pantheon of Rome, which was erected under Augustus, and is still perfect. A list of the domes whose dimensions entitle them to notice is here subjoined:—

Domes	Internal	
	Diameter	Height
	ft.	ft.
Pantheon at Rome . . .	142·6	143
Baths of Caracalla . . .	112	116
Duomo of Florence, Sta. Maria del Fiore . . .	139	310
St. Peter's at Rome . . .	139	330
St. Sophia, Constantinople . . .	104	201
St. Paul's, London . . .	112	216
Dome of the Mosque of Achmet . . .	92	120

Domes	Internal	
	Diameter	Height
	ft.	ft.
Chapel of the Medici . . .	91	199
Baptistery of Florence . . .	86	110
Church of the Invalides, Paris . . .	80	173
Minerva Medica at Rome . . .	78	97
Madonna delle Salute, Venice . . .	70	133
St. Geneviève, Paris . . .	67	190
Duomo at Sienna . . .	67	148
Duomo at Milan . . .	57	264
St. Vitale at Ravenna . . .	55	91
Val de Grace at Paris . . .	55	133
St. Mark's, Venice . . .	44	150
Halle aux Bles, Paris . . .	131	150
St. Isaac, Petersburg . . .	96	150

Domesday Book (*Liber Judiciarius*, or *Censualis Anglia*). Was framed by order of William the Conqueror, and contains a general survey of most of the lands in England, their extent in each district, their proprietors, tenures, value; the quantity of meadow, pasture, wood, and arable land which they contained; and, in some counties, the number of tenants, cottagers, and slaves of all denominations who lived upon them. The meaning of the term *domesday* is still disputed. (Hallam, *Middle Ages*, ch. ix. part ii.)

Domesday Book consists of two volumes; one in fol., the other in 4to.: the former comprehending thirty-one counties, the latter those only of Essex, Norfolk, and Suffolk. The counties of Northumberland, Cumberland, Westmoreland, and Durham were not comprehended in this survey, probably on account of their then wild uncultivated state. Nor does Lancashire appear under its proper name; but Furness and the northern part of that county, as well as the south of Westmoreland and part of Cumberland, are included within the West Riding of Yorkshire. Though in several respects the information contained in Domesday Book is inaccurate and defective, still it serves admirably to illustrate the ancient state of England. The publication of Domesday Book was undertaken by order of George III. in 1767, and was completed, under the superintendence of Mr. Abraham Farley, in 1783. The original is deposited in the Record Office. Sir H. Ellis has published a useful introduction and index to it. Two volumes of Records supplementary to Domesday Book, framed for a similar purpose, and of a nearly contemporary date, were published in 1816 by the Commissioners upon the Public Records. The printing of these works was in facsimile, as far as Roman types, assisted by the representation of the mediæval contractions, could be made to imitate the original. But those lately produced in photozincography, by Sir Henry James, of the Ordnance Survey Office, Southampton, completed at the end of 1863, of course are perfect facsimiles. The following are the abbreviations used in Hutchin's *Domesday Book* for the county of Dorset:—

DOMICILE

<i>ac̄, acra.</i>	<i>p, pro.</i>
<i>accla, ecclesia.</i>	<i>ht, habet.</i>
<i>arch, archiepiscopus.</i>	<i>ppt̄, propter.</i>
<i>car̄, caruca, carucata.</i>	<i>q̄t̄ xx^u 7 ix, 89.</i>
<i>dim̄, dimidium.</i>	<i>q̄, quæ.</i>
<i>dñio, dominio.</i>	<i>q, qui.</i>
<i>ead̄, cadem.</i>	<i>q̄, quo.</i>
<i>7, it.</i>	<i>q̄z, quarent^u, q̄rent,</i>
<i>ē, est.</i>	<i>quarentena.</i>
<i>eccliam, ecclesiam.</i>	<i>q̄dā, quædam.</i>
<i>ep̄us, episcopus.</i>	<i>redd̄, reddunt, reddit.</i>

<i>p^{ti}, prati.</i>	<i>un^s, unus.</i>
<i>ptin^t, pertinet.</i>	<i>ũ, vero.</i>

Domicile. In Law, the place where a person has his home. Personal property, on the decease of the owner, is distributable according to the law of the country in which he was domiciled at the time of his death; not according to the law of the country in which the property is situate. Residence for forty days constitutes a domicile as to jurisdiction in Scotland.

Dominical Letter. For the purpose of exhibiting the day of the week corresponding to any given day of the year, the framers of the ecclesiastical calendar denoted the seven days of the week by the first seven letters of the alphabet, A, B, C, D, E, F, and G; and placed these letters in a column opposite to the days of the year, in such a manner that A stood opposite the 1st of January or first day of the year, B opposite the 2nd, and so on to G, which stood opposite the 7th; after which A returns to the 8th, and so on through the 365 days of the year. Now if one of the days of the week, Sunday for example, falls opposite to E, Monday will be opposite to F, Tuesday G, Wednesday A, and so on; and every Sunday through the year will be represented by the same letter E, every Monday by F, and so on. The letter which represents Sunday is called the *Dominical Letter*, or *Sunday Letter*. As the number of days in the week and the number in the year are prime to each other, two successive years cannot begin with the same day; hence

DOOR

the Dominical Letter changes every year. This mode of representing the days of the week has now fallen nearly into desuetude, and the initial letter of the name of the day is placed in our almanacks opposite the day of the month.

Dominicans. Friars of the order of St. Dominic, instituted at the beginning of the thirteenth century. [ORDERS, MENDICANT.]

Domino (Ital.). A long loose cloak of black silk, furnished with a hood removable at pleasure, and worn chiefly at masquerades by persons of both sexes by way of general disguise. [MASQUERADE.]

Domite. A volcanic rock (porphyritic trachyte) forming the Puy de Dôme, in Auvergne.

Don (Lat. dominus). A Spanish title, which the king, the princes of the blood, and the highest class of the nobility prefix to their names. The title *donna* given to ladies represents the Latin *domina*.

Donatists. A religious faction, which arose in Africa in the beginning of the fourth century in opposition to Cecilianus, bishop of Carthage. The Numidian bishops were indignant at a slight received from him at the time of his consecration, and declared him informally appointed, on account of their absence from the ceremony. They also accused him of unworthy conduct during the Diocletian persecution. There are two persons of the name of Donatus celebrated as leaders of this party. Their cause was heard before several councils (those of Arles, Milan, and Carthage), in all of which they were pronounced schismatics. The Donatists, however, continued to be a powerful faction for more than one hundred years, and raised at various times great wars and commotions. The name CIRCUMCELLIONES [which see] was given to the numerous bands of country people of the lowest ranks who took up arms in their cause. St. Augustine was most successful in bringing public opinion to bear against the Donatists.

Donative (Lat. donativum). In Law, a benefice merely given and collated by the patron, without presentation, institution or induction. This, it is said, was the original way of conferring benefices in England, the interference of the bishop being a later encroachment, ascribed by some to Becket.

Donjon or Dungeon. Originally a fortress on a hill: from the Celtic dun, *height*. The central building or keep of an ancient castle; frequently raised on an artificial elevation.

Donkey Engine. A small engine used to supply water to the boilers of large engines, or to perform some minor works, when the large engine is not in full operation.

Door (Gr. *thura*, Ger. *thor*, Sansc. *dvār*). In Architecture, this word is applied to the gate or the entrance to a house, or to the means by which access is obtained to the inner apartments on the same floor as the bottom of the door. The door frame is the surrounding case into and out of which the door shuts and opens. It consists of two upright side pieces,

DORADO

or posts, and a head, generally fixed together by mortices and tenons, and wrought, rebated, and beaded. The door itself is either panelled on both sides, with mouldings in the panels, or it may be finished square, bead flush, bead butt; it may be either a ledged door, a clamped door, or a framed door.

Dorado (Span. *gilt*). A southern constellation, formed by Bayer; called also sometimes the *Sword-fish*.

Dorema (Gr. *a gift*). The name of certain umbelliferous plants from Persia, one of which, *D. ammoniacum*, furnishes the drug *Ammoniacum*. The plant abounds in a milky juice, which exudes on the slightest puncture, and dries in the form of little rounded lumps or tears. The ammoniacum of the ancients has, however, been ascribed to *Ferula tingitana*.

Doric Order. In Architecture, one of the five orders. The true origin and birthplace of this order are not known. The example here

given is from the temple of Theseus at Athens, which is considered one of the best examples of Grecian Doric. The principal points in which the Grecian differs from the Roman Doric are, that the former stands at once on the pavement of the building, without socle, tori, or fillets; and that it presents a more pyramidal section than the latter, from the great diminution given to it. Its flutes, too, are never deeply sunk; the capital has no astragal, but only some annulets to separate it from the shaft. The entablature is so subdivided that the architrave and frieze are each more than a third of its height, the remainder being given to the cornice, which has a band under the mutulus. The mutulus projects forward under the corona, over which is generally placed an ovolo and a fillet, with a larger ovolo and fillet above them; the column is usually five or six diameters high. The principal examples of this modification of the order are the Parthenon, temple of Theseus, Propylæum, portico of the Agora at Athens, the temple of Athena at Sunium, one at Corinth, temple of Apollo and portico of Philip in the island of Delos, &c. The Roman Doric differs considerably from that above described, as will be seen by comparing the drawings of the two. From the diagram of the Roman modification of the order, it will be seen that the triglyphs are always placed over the centre of the columns, and the metopes should form an exact square. It follows, then, that the intercolumniations are always regulated by the triglyphs. Sometimes the column is placed

DORSIBRANCHIATES

on a plinth, at other times on a pedestal sparingly decorated with mouldings. Though

it occasionally, as in this example, has an Attic base, it is more commonly used with only a torus and an astragal. The capital is formed with a neck and astragal under the ovolo, and a cyma reversa and fillet on the abacus. The only pure ancient example of this order is that of the theatre of Marcellus at Rome; the flutes are without fillets between them, as in the Grecian

Doric, and are twenty in number. Of the modern architects, by far the most successful in his profile of the order, which has been converted into what may be called the Italian Doric, is Palladio, from whose works the example given above is extracted.

Dorippe. A genus of the short-tailed Decapod Crustaceans, belonging to the tribe *Notopoda*. The species of this genus exist at great depths in the sea, and it is probable that they use the small feet, which are directed towards the back, to cover themselves with foreign bodies for concealment: they have been found in the Mediterranean, Adriatic, and Indian seas.

Dormer (Fr. *dormir*, to sleep). In Architecture, a window inserted on the inclined plane of the roof of a house, the frame being placed nearly vertically with the line of the rafters. The Gothic architects frequently made their dormer windows an important detail in their compositions. The word originally signified a *sleeping apartment*.

Dormitory (Lat. *dormitorium*, from *dormio*, I sleep). In Architecture, a large sleeping apartment capable of containing many beds.

Dormouse (Lat. *dormio*, I sleep). A genus of Rodent Mammalia, in which the hibernating faculty is exceedingly developed. Three species are known in Europe, the Loir (*Myoxus Glis*), the Lerot (*Myoxus Nitela*), and the Muscardin (*Myoxus avellanarius*). The last and smallest species is the one which is most common in England.

The last syllable of the word *dormouse* is probably nothing more than false etymology. In Suffolk this animal is called a *sleepy*. [*Glis* and *Myoxus*.]

Dorneck. A stout figured linen, named after the town in Scotland where it was originally manufactured.

Dorsibranchiates, Dorsibranchiata (Lat. *dorsum*, back; *branchia*, gills). A name given by Cuvier to an order of Anellidans, or

ted-blooded worms, comprehending those which have the gills projecting from the middle part of the back or sides of the body. The Nereis, or sea-centipede, is an example of this order.

Dort, Synod of. An assembly of Protestant divines convoked at Dort in 1618-19, by the States-General, under Maurice, prince of Nassau, in which the tenets of the Arminians on the five points relating to election, redemption, original sin, effectual grace, and perseverance, were condemned by the adherents of Calvinism. This national synod consisted of thirty-eight Dutch and Walloon divines, five professors from different universities, and twenty-one lay elders; but besides these there were ecclesiastical deputies present from most of the states of the United Provinces, and from the churches of the Palatinate, Hesse, Switzerland, Bremen, England, and Scotland. This synod was opened on November 13, 1618, and continued till May 29 in the following year, during which period it held 180 sessions; but long before these sessions had come to a close, the Arminians were condemned as corruptors of the true religion. It was at this synod that the project of obtaining a translation of the Bible into Dutch was first started. The execution of this task was intrusted to some of the most learned men of the time; and after the lapse of nineteen years their labours were given to the world in what has been since known as the *Dort Bible*. [ARMINIANS.]

Dositheans. The name of a religious sect which sprang up in the first century of the Christian era. Their principal tenets consisted in believing in the divine mission of their leader, Dositheus, from whom they derived their name, and in rejecting the authority and inspiration of the prophets.

Double Bass. [CONTRABASSO.]

Double Dagger. In Printing, a character marked thus †, used as a reference to notes in the margin of the page.

Double Letters. In Printing, those types, such as the f, i, and l, which, when used in combination, are apt to be broken in locking up the form of types. They are therefore cast in one piece, or logotype, as ff, fi, fl, &c. The diphthongs æ and œ are also cast as double letters.

Double Pica. [PICA.]

Double Point. In the theory of curves, a point through which the curve passes twice. [NODE.] Of the infinite number of lines through a double point, all of which meet the curve in two coincident points, there are two, and only two, which meet the curve in three coincident points; these are the *tangents at the double point*. When these tangents are real and distinct, the point is frequently called a *node*; when real and coincident, a *cusp*; and when imaginary, a *conjugate or isolated point*. A plane curve of the n^{th} order will not have double points unless the discriminant of its equation vanish, and a proper curve of this order cannot have more than $\frac{(n-1)(n-2)}{2}$ double points. Every double point

of a curve is also a double point on its Hessian,

and both these curves have the same tangents at each such point.

In the theory of surfaces, a point is said to be a double one when the surface is there cut by any right line whatever in two coincident points. Through such a double point an infinite number of lines can be drawn, each of which will meet the surface in three coincident points; and as all such lines lie on a tangent cone, a double point is sometimes called a *conical point*, and sometimes also a *node*. The terms *biplanar node* and *uniplanar node* are used to distinguish the cases where the cone in question breaks up into two distinct, and into two coincident planes. [NODE.] A curve every point of which is a double point on the surface is called a *double or nodal line or curve*. The condition that a surface should possess double points is found by equating to zero the discriminant of its equation.

Double Points of an Involution. [INVOLUTION.]

Double Stars. [STARS, DOUBLE.]

Double Tangent Line of a Surface.

A line which touches the surface twice or in two pairs of coincident points. To possess double tangent lines, it is clear that the order of the surface must exceed the third; when this condition is fulfilled, however, it will be possible to draw innumerable such lines; in fact, $\frac{1}{2}n(n-1)(n-2)(n-3)$ double tangent lines of a surface of the n^{th} order will, in general, pass through any point in space, and there are $(n+2)(n-3)$ such lines which have one of their points of contact coincident with a given point, and which, consequently, lie in the tangent plane at that point.

Double Tangent Plane. A plane which touches a surface, or a non-plane curve, twice. A surface of sufficiently high order, say n , has an infinite number of double tangent planes, since a plane requires but three conditions for its complete determination, and their points of contact lie on a curve of the order $n(n-2)(n^3-n^2+n-12)$. The number of double tangent planes which pass through any point in space is

$$\frac{1}{2}n(n-1)(n-2)(n^3-n^2+n-12).$$

(Salmon's *Analytical Geometry of Three Dimensions*.)

Double Tangent of a Plane Curve.

A line which touches the curve twice, that is to say, a line which meets the curve in two pairs of coincident points. It is obvious that only curves of the fourth or of higher order can possess double tangents. The latter, however, will, in general, possess them, since a right line can be made to satisfy two conditions. The points of contact of a double tangent may be imaginary, real and distinct, or real and coincident. We may conceive the last case to arise when of the *tangentials*, or points in which a simple tangent cuts the curve again, one coincides with the point of contact; so that a double tangent with coincident points of contact must be regarded as a *stationary tangent*, and its point of contact a *point of inflexion*. The

subject of double tangents has been treated by Plücker (*Theorie der Alg. Curven*, 1839), who first showed that a curve of the n^{th} order has in general $\frac{1}{2}n(n-2)$ (n^2-9) such tangents; by Jacobi, Hesse, Steiner, and others (*Crelle's Journal*); and finally, by Salmon and Cayley (*Phil. Mag.* 1858, and *Phil. Trans.* 1859), who gave the complete solution of the problem which requires their determination.

Double-acting Pump. A pump that lifts and forces water alternately on each side of the course, by means of a solid piston or plunger, and an entrance and exit valve, communicating with each side.

Double-banked. In speaking of rowing, signifies that the rowers sit side by side in twos, a pair of oars being worked from each thwart. This can only be practised in wide boats.

Doubleloo. [MONST.]

Douche (Fr.). A jet or current of water directed upon some part of the body. An apparatus for this purpose is to be found in most bathing establishments. Steam or vapour is also sometimes applied in the form of douche.

Dovecot. A structure for keeping tame pigeons; the only essential difference between which and a common poultry-house is, that the entrance for the birds must be raised to a considerable height from the ground, because pigeons fly higher in the atmosphere than most other birds.

Dover's Powder. A compound of ipecacuanha, opium, and sulphate of potash. It is the *pulvis ipecacuanhæ compositus*, or compound powder of ipecacuanha, of the Pharmacopœia. Ten grains, which is the average dose, contain one grain of opium and one of ipecacuanha. It is an excellent sedative and sudorific.

Dovetail. In Architecture, a joint used by carpenters in connecting two pieces of wood, by letting one piece into the other in the form of the expanded tail of a dove. It is the strongest way of joining masses, because the tenon or piece of wood widens as it extends, so that it cannot be drawn out, because the tongue is larger than the cavity through which it would have to be drawn. The French call this joint a *queue d'hirondine*, or swallow's tail.

Dowager (Fr. *douairière*). A widow endowed: that is, who either enjoys a dower from her deceased husband, or has property of her own brought by her to her husband on marriage (dowry), and settled on herself after his decease. In the language of etiquette the term is applied to a widow lady, to distinguish her from the wife of her husband's heir having the same title.

Dowel. The name given originally to a pin used horizontally for joining two pieces of material, the dowel being inserted in its socket on the one piece before the other substance with the socket is forced into its place. When used in stone-work, the dowels are subsequently run with cement, or lead, and occasionally with sulphur.

Dower (Low Lat. *dotarium*, from *dos*). In Law, is defined to be the estate for life which a

widow acquires in a certain portion of her husband's real property after his death. Dower by the common law entitles her to a third part of all the lands and tenements of which the husband was seized in fee simple or fee tail at any time during the coverture. Hence this species of dower could not be affected by the husband's conveyance of the lands, unless by fine or recovery in which the wife joined, or by his devise. But the law in this respect has undergone material alteration by the provisions of the 3 & 4 Wm. IV. c. 105. Dower by custom varies in different districts. There were other obsolete species of dower, now abolished by the statute already mentioned. A married woman may be deprived of her right to dower by attainer of her husband for treason, or herself for treason and felony; by divorce à vinculo matrimonii; by elopement from the husband and living with an adulterer, which incapacity may be removed by the reconciliation with the husband. In order to prevent the inconveniences occasioned by this right, which materially impeded the conveyance of property, various modes of *barring*, i.e. defeating, the right to dower were invented by legal ingenuity, and are still adopted, for that purpose, in conveyances of land to persons married before Jan. 1, 1834. The above-mentioned Act applies to all persons married after that date, and enables the husband to dispose of his lands free from any claim of dower on the part of the wife.

Dowlas. A coarse kind of linen.

Downs. Have been defined to be banks or elevations of sand which the sea gathers and forms along its shores, and which serve it as a barrier. The word is derived from the Celtic *Drwnes* [which see]. The term is also applied to large tracts of poor naked hilly land which serve chiefly for the grazing of sheep, thence called *down sheep*.

Downs is also the name given to the well-known road for shipping in the English Channel, which possesses excellent anchorage, and in time of war forms the place of rendezvous for the English navy.

Dowry. Although often confounded with *dower*, has a different meaning; namely, the *dos mulieris* or marriage portion brought by the wife to her husband. The word, however, has no legal significance.

Doxology (Gr. *δοξολογία*). A form of praise or glorification. The greater and lesser Doxologies, as they are distinguished by the liturgical writers, are the angelic hymn, 'Glory be to God on high,' &c.; and the shorter form, 'Glory be to the Father,' &c. The last clause in the Lord's Prayer, as given by St. Matthew, the genuineness of which has been sometimes questioned, is also frequently called the Doxology.

Drachm (Gr. *δραχμή*). There are two drachms in our system of weights; namely, the avoirdupois drachm, which is the sixteenth part of the avoirdupois ounce; and the apothecaries' drachm, which is the eighth part of the troy ounce, and equivalent to sixty troy grains: the

DRACHMA

latter drachm is the only one which is retained in common use.

Drachma (Gr. *δραχμή*). An Athenian silver coin of the value of six oboli, or about $\frac{7}{8}$ d. of our money. Other Greek states had *drachma* of different values, but the above is that generally referred to. There was also a weight of this name nearly equivalent to 2 dwt. 7 gr. troy weight.

Draco (Lat. *the Dragon*). One of the ancient constellations in the northern hemisphere.

Draco Mitigatus (Lat.). An alchemical name of *calomel*: corrosive sublimate was probably called *draco* or the dragon.

Draconin or **Dracina**. The colouring matter of the resin called *dragon's blood*.

Draconyl. A hydrocarbon obtained from dragon's blood resin.

Dragomans. The interpreters attached to European embassies or consulates in the Levant. The dragoman of the Sublime Porte is an important Turkish officer, who forms the medium of communication between his own government and the embassies of foreign countries.

Dragon (Gr. *δράκων*). One of the most famous mythological creations of antiquity and the middle ages. It occurs in the sacred allegories of the Jews, and in the legends of the Chinese and Japanese; and the pages of the poets of Greece and Rome teem with representations of the dragon. Thus the dark retreats of their gods and their sacred groves were defended by dragons. In the Vedic mythology, the dragon Vritra is the antagonist of Indra; and in the Greek myths, a dragon kept the garden of the Hesperides, &c. In the Scandinavian mysteries, the dragon was the minister of vengeance under their vindictive gods. (Grimm's *Deutsche Mythologie*.) The allegory of the Dragon has also found a place among many nations who have embraced Christianity. In the Book of Revelations, the angel is represented as laying 'hold on the dragon, that old serpent, which is the devil;' and hence in painting and statuary the triumph of Christianity over infidelity and heathenism is sometimes represented by a dragon pierced or trampled under foot. This representation forms also the attribute of different saints, in the legends of Christianity, more especially of St. Michael and St. George. On the origin of the Dragon in mythology, see Max Müller's 'Comparative Mythology' in *Oxford Essays* for 1856, p. 66 &c.; Bréal, *Hercule et Cacus*.

DRAGON. In Zoology, this term is applied to a genus of small Saurian reptiles, characterised by two lateral aliform productions of the skin supported upon the first six pairs of ribs; which, instead of bending round the thorax, are elongated and directed outwards for that purpose.

Dragon Beam. In Architecture, a horizontal piece of timber upon which the hip, or angle rafters of a roof, pitch. It is framed into a short diagonal piece which ties the plates at the internal angles of a roof. Pro-

DRAIN

perly speaking, this should be written *dragging piece*.

Dragon Fly. A common name for the Neuropterous insects belonging to the genus *Agria* or *Libellula*.

Dragon's Blood. A deep red resin used in colouring varnishes; it is the produce of the *Pterocarpus draco*, and is imported from India.

Dragon's Head. In Heraldry, part of the celestial constellation *Draco*, used in ancient English emblazonments to denote tenné, or orange-colour, in the arms of sovereigns. The *Dragon's tail* was also used to denote sanguine.

Dragonnades (Fr.). The name given to the persecutions instituted by Louis XIV. and his successor against the French Protestants, from the coercive measures (*parcours* ou *y employait les dragons*) which were put in force to effect their conversion.

Dragonnée (Fr.). In Heraldry, a lion or other beast whose upper half resembles a lion, &c., but the lower half that of a dragon.

Dragoons (Fr. *dragon*; probably so called from the musket, *Dragon*—in English, *Drake*—which they carried: Markham's *Souldier's Accidence*, 1645). The name given to a species of cavalry originally trained and armed to act either on foot or on horseback, as emergencies might require. The origin of this species of troops has been ascribed by Père Daniel to the *maréchal de Brissac*. They were at first armed with pikes and muskets. In 1682 we find the pike gone, and a sword substituted; gradually they ceased to act as infantry, and became armed as now with carbine and pistols, and the sword for their chief weapon. At present dragoons form part of the military force of all the powers of Europe. The first regiment of dragoons in this country was raised in 1681, and called the Royal Regiment of Dragoons of North Britain, now the *Scots Greys*. In England, there are *dragoons* and *dragoon guards*; the difference between them consisting in this, that the accoutrements and horses of the latter are somewhat heavier than those of the former. [CAVALRY.]

Drain. A channel on or below the level of the ground by means of which water is conveyed to the principal discharging course of the district. According to the nature of the water so to be removed, a drain may be open or covered, permeable or impermeable; and according to the importance which the parts of a system of drainage bear to the whole, they are called *main* or *arterial drains*, and *subsidiary drains*. When used for removal of the waste waters of towns, main drains have latterly been very incorrectly named *sewers*, whether they be open or closed; the conduits for the relief of separate premises being specifically known as *drains*. For agricultural drainage, pipes made of clay of from one inch to six inches diameter are used; for house drainage the pipes are made from six inches to twelve inches in diameter: the inclination to be given to a six-inch house drain should

be at least one in eighty, in order to keep it clear.

Draining. In Economic Geology. So far as it depends on geological structure, draining is one of the departments of practical or economic geology. Surfaces are naturally drained by rills and streams worn on the surface by running water; but it is evident that this can only be the case when there is a slope. When also the natural slope is interfered with by barriers of rock, or by accidental obstructions, water will accumulate and require to be got rid of. Such drainage sometimes takes place by natural fissures. If this is not the case, various contrivances are necessary, depending greatly on geological conditions. On a large scale these operations require engineering operations.

Drainage of soils may sometimes be effected by opening a communication with some permeable rock below. More frequently advantage must be taken of the form of the surface to carry the water from a higher to a lower level, whence there is a natural outfall to the sea. When water meanders through a clayey district, or one of which the surface is soft, there is a tendency to increase the windings. This can, however, be counteracted by artificial cuts. The water naturally takes the shortest way, its current is increased in the short cut, and, part of the sluggish water still slowly permeating, the curve tends to silt up the old channels. Thus a systematic drainage will help itself, and recover a former good channel closed by interruptions.

Drainage not only carries away superfluous water, but actually deepens and improves a soil, besides being an important preparation for engineering and architectural works. No foundation can be stable, and no building free from the chance of dry rot, if attention is not paid to the drainage and the geological circumstances of the site.

Faults are important adjuncts in reference to ordinary and natural drainage. Some are pervious to water, and carry water for long distances where it would least be suspected. Others are impervious, and keep water back. Attention to the structure of a district in this respect is necessary to enable the architect or engineer to understand natural drainage.

The drainage of mines is generally carried on by means of steam engines lifting the water in the mines to the lowest level at which an outfall can be secured to a river or the sea. Coal mines are often enabled to escape much pumping by very carefully shutting out the water met with in sinking; but metal mines cannot generally be thus managed.

Systematic draining on a large scale is essentially a branch of engineering; and we have only noticed the subject in its geological bearings to point out how much one department of science may sometimes be assisted by another.

Dram Timber. The balk timber that comes from Dram, in Norway, is known under this name in the timber trade.

Drama (Gr. δράμα, *an action or thing done*). A species of poem in which the action or narrative is not related, but represented.

The elements of the dramatic art in Greece were found in the religious festivals celebrated from the earliest ages in that country. The feasts of Dionysus (Bacchus) in particular had sacred choruses or odes; these were afterwards intermixed with episodic narrations of events in mythological story, recited by an actor in the festival with gesticulation. The next step was to introduce two actors with alternate recitation; and thus were produced **TRAGEDY** and **COMEDY** [which see]. In the latter, the dialogue of the interlocutors was satirical; in the former, mythological. The early Greek tragedy was a dramatic representation of some scenes or events recorded in the national traditions, the actors personating those who played a part in these events, together with a chorus or band of singers, representing such persons as might naturally be supposed to have been bystanders at the occurrence (captive women, old men, or counsellors, &c.), who sang at intervals, during the representation, hymns to the gods, or songs appropriate to the scenes passing in representation: while the Attic comedy, in its first invention, must be regarded as a parody on tragedy, in which the personages were either real characters introduced for the purpose of satire, or ludicrous personifications. Æschylus, the oldest tragic writer (with the exception of Phrynichus, his contemporary), carried the Greek drama at once to nearly its highest state of perfection. Sophocles and Euripides introduced additional actors into the dialogue (which at first admitted only two at the same time), and turned the naked recitals of events which form the substance of the plays of Æschylus into something more nearly resembling the modern idea of a plot, with contrasted characters and incidents leading to the accomplishment of a main action. Many tragic writers, the whole of whose works have been lost, flourished after Euripides in Athens and Alexandria; but they do not seem to have altered the character of the art which they received from their predecessors. The fate of comedy was different: the old Attic comedy was a political or philosophical satire in action, which in form was a burlesque on the tragedy. Afterwards, passing through the intervening stage of the middle comedy, of which we know little, the art acquired in the new comedy of Menander and Philemon a character somewhat approaching to that in which it is at present cultivated; a representation of scenes and incidents in ordinary life, of a light or ludicrous character.

From the rules of criticism delivered to us by Greek authors, and especially by Aristotle, it appears that the parts or characteristics of a tragedy, essentially divided, were held to be the fable or story, the manners, the style, the sentiment, the music, and the diction: that the fable should consist of an entire action, namely, one principal event with its auxiliary events; and that the proper emotions to be excited by

DRAMA

the action are terror and pity. Its parts of quantity, according to the division of form, were the *prologue*, being that part of the tragedy which precedes the parode or first entry of the chorus; the *episode*, being all those several parts which are included between the several choral odes; the *exode*, the part which follows the last choral ode; and the chorus itself, or the intervening odes, which also admit of various subdivisions. Formally considered, the arrangement of the old comedy nearly resembled that of tragedy; in the new, the chorus was altogether omitted. The unity of action was a remarkable characteristic of the Greek drama; but it should rather be termed unity of subject, inasmuch as in many of our remaining tragedies, and especially those of Æschylus, there is little or no trace of what we term a *plot*, i. e. a main incident at which we arrive through subordinate incidents tending to its accomplishment. The unity of time—viz. that the imaginary duration of the action should not exceed twenty-four hours; and that of place—namely, that the scene in which the events occur should be the same throughout—are inventions of French critics, not warranted by the remains of Greek art, in which both are not unfrequently violated; but, although not rules of Grecian discovery, they are easily rendered applicable to the simple and severe form of the Greek tragedy.

In considering the theatrical effect of the Greek drama, we must remember that the tragedies were originally religious solemnities; the theatre, a vast building open at the top, accommodating several thousand spectators. Dramatic representations were, at Athens, the offering of wealthy men to the people: he who contributed the expenses of the entertainment was said, *elodyeur*, to bring in the play; the poet who produced it, *didaskur*, to teach it, i. e. teach the actors to perform it. A complete representation consisted of four pieces by the same author: a *trilogy*, or three tragedies, continuing the same subject; and a fourth piece, termed a *satyrical drama*, of which the chorus consisted of satyrs, and the subject was treated in a manner approaching to burlesque. The features of the actors were exaggerated by masks, their height increased by dress, and their powers of voice aided by acoustic contrivances, in order to suit the colossal dimensions of the theatre. The whole vocal part was rhythmical; the choral odes were sung, and accompanied by the choric dance, in which the actors composing the chorus took part, subjected to very peculiar rules: the narrative part of the performance was spoken in a peculiar modulated voice, resembling probably the recitative of the modern opera.

Latin Drama.—The early Etruscans possessed dramatic representations, whence the Romans derived some peculiar national entertainments [*MIMI*]; but, with this slight exception, their drama consisted merely in the first instance of translations, afterwards of close imitations of the Greek. In the degeneracy

of the Roman empire even this adscitious taste ceased to be cultivated, and the theatres were entirely occupied by farcical buffoonery, or shows and sports on a gigantic scale. Among an infinite variety of works which treat of the classical drama, may be cited the first volume of Schlegel *On Dramatic Art and Literature*. A catalogue of them will be found at the end of the fourth edition of Donaldson's *Theatre of the Greeks*.

Chinese Drama.—In China, theatrical entertainments form one of the most popular amusements, and theatrical writing has been cultivated from a very early period. The Chinese drama comprises pieces which we should term both tragical and historical plays, tragi-comedies, and comedies both of intrigue and of manners; together with abundance of low, pantomimic, and farcical representations. In their regular drama, however, there appears to be less of what we should term connected than of successive action: many of them are, as it were, dramatised memoirs or biographies of individuals, real or fictitious; the representation of some is said to require ten days. It is remarkable that, of all national dramas, the Chinese appears to be the only one in which we can trace no original connection with religious observance. (Morrison, *Horæ Linicæ*; Abel Remusat; *Memoirs of the Académie des Inscriptions*, &c.)

Hindu Drama.—The Hindu plays which now exist are written for the most part in Sanscrit, although not a living language at the period when they were composed. The dramatic art appears to have flourished in India during a period of several ages, ending about the fourteenth or fifteenth centuries of our era. Dramatic criticism was also much cultivated; and the most minute and artificial rules are laid down by Hindu commentators as to the conduct of a piece, the requisite ethics, the formal arrangement, and the characters which must be introduced. The Hindu drama is so widely different from the Greek or Chinese, that it must be regarded, like them, as a spontaneous offspring of national genius.

Modern European Drama.—For many centuries after the downfall of the Roman empire, the dramatic art appears to have been entirely lost. Its first revival in the middle ages was owing to the solemnities of the church, into which dramatic interludes were introduced in various countries of Western Europe, representing at first events in biblical history or the lives of the saints, and afterwards intermingled with allegorical fantasies. [*MYSTERIES; MORALITIES.*] At the period of the revival of literature, however, the dramatic art was called into life nearly at once in the four principal countries of Western Europe; Italy, France, Spain, and England. In Italy and France it arose simply classical, and unmixed with any original conceptions, or with the sentiments and fashions of the middle ages; in Spain and England it partook largely of both, and was also immediately derived from the mysteries

DRAMA

and moralities above mentioned: hence, in a historical view, arose the distinction, so elaborately explained by modern critics, between the classical and romantic drama.

Italian Drama.—Originated in close imitation of classical models. The pastoral drama of the sixteenth century, of which Tasso and Guarini were the most celebrated writers, furnished the first novelty in this branch of literature; but these are rather poetical than dramatical compositions. The true national theatre of Italy arose in the seventeenth century, in the musical drama (opera), to which Metastasio, early in the eighteenth, communicated all the charms of poetry; but since the period of that writer, the operatic part of the dramatic art has again been wholly disconnected from the literary, and the words only serve as vehicles for the music. While the higher classes were devoted to the opera, the lower found their national amusement in the *commedie del' arte*, comedies performed by masqued characters, which gradually became fixed in the well-known persons of Harlequin, Pantaloon, Brighella, &c., who improvised their parts. Goldoni, in the middle of the eighteenth century, succeeded in establishing a regular comic drama in possession of the stage; while his rival, Gasparo Gozzi, took up the *commedie del' arte* as models, and founded upon them a series of amusing extravagances. But since the period of these two spirited writers, comedy has fallen almost completely into disrepute. At the end of the eighteenth century Alfieri, a bold and severe genius, produced tragedies in which the ancient classical form (with the exception of the chorus) was again reverted to, instead of the French imitations of it which had long been current in Italy as well as the rest of Europe; and several dramatic poets have since appeared, who have adopted the same model.

French Drama.—The early French tragic writers, from the beginning of the sixteenth century down to Corneille in the middle of the seventeenth, produced nothing but unsuccessful and somewhat barbarous imitations of the Greek tragedy. The first pieces of this kind represented on the French stage had prologues and choruses. The French tragedy grew up with Corneille and Racine as models, and Boileau as its legislator. A peculiar and rigorous system of criticism was introduced, affecting both the form and the substance of dramatic writing; and this system became established in the minds of the French public, as the natural and not the conventional rule of beauty. It would be impossible to enter into an examination of the rules of the French drama; suffice it to say, that they banished from the tragic stage all except heroic characters and passion; required perfect simplicity of plot, uniformity of language, and, in addition, the observance of the before-mentioned technical unities of place and time. These rules have ever since been scrupulously followed, without deviation, on the regular French stage.

The French comedy, however, is infinitely more national and characteristic than the French tragedy: it originated in that of Spain, and was carried at once to a high degree of perfection by Molière, retaining satire instead of adventure as its leading principle. Since that period the French comic stage has been, beyond all contradiction, not only the best, but the model from which that of all other nations has been wholly derived. Of the present state of the French drama it is difficult to speak with precision; but the national or regular stage seems to be every day losing in popularity, while the attempts to establish a new one on what is termed in France the romantic model have hitherto met with very partial success.

Spanish Drama.—Spain commenced her literary career more independent of foreign aid than any other country. Her dramatic art appears to have originated as early as the fourteenth century, which produced satirical pieces in dialogue, and one complete dramatic romance by an unknown author (*La Celestina*), in addition to the mysteries and miracle plays, which were exhibited in Spain even more plentifully than elsewhere. The early Spanish comedies of the sixteenth century were conversations like eclogues, between shepherds and shepherdesses; with occasional interludes of negroes, clowns, and Biscayan, the favourite subjects of popular jest. But the Spanish drama owed to one great author, Lope de Vega, what our own owed to his contemporary, Shakspeare—a rise at a single bound from insignificance to great richness and variety. Calderon, a greater poet than Lope, and his equal in dramatic power, is the only other great name in the Spanish drama. Subsequent writers may all be classed as imitators either of their own older poets, or of the favourite dramatists of the French school.

English Drama.—For the semi-religious representations out of which the English drama arose, see MYSTERY and MORALITY. One of the latter, *The New Custom*, was printed as late as 1673; by which time several regular tragedies and comedies, tolerably approaching to the classical model, had appeared. But a third species of exhibition soon took possession of the stage, the historical drama, in which the successive events of a particular reign or portion of history were represented on the stage; and, together with it, arose the English tragedy and comedy. Our first dramatic poets (those before Shakspeare) were scholars; hence they preferred the form of the ancient drama, the division into acts, &c. But they were also writers, who strove for popularity with the general class of their countrymen; hence, instead of imitating classical simplicity, and confining themselves to a peculiar cast of diction and sentiment removed from the ordinary course of life, they invented a species of composition which intermingled poetical with ordinary life and language. Comedy, again, became in their hands a representation of adventures, differing from those of tragedy only

DRAMA

by ending generally in a happy instead of an unhappy exit, and not materially either in the characters or language. Thus the distinctions which they established between tragedy, comedy, and tragic-comedy, are little more than adventitious; and the Shakspearian drama, properly considered, must be looked on as a miscellaneous compound in which actors, language, and sentiments, of a character far removed from those of ordinary life, alternate with those of a low and even a burlesque character. There is no tragedy of Shakspeare in which comic scenes and characters are not introduced: there is only one comedy (*The Merry Wives of Windsor*) without some intermixture of sentiment approaching to tragic. It continued to be the chief national literature, as well as the favourite national amusement, down to the period of the civil wars, when the opinions and legislation of the prevailing party put a stop to dramatic representation altogether. During the interval thus created the old English art was unlearned altogether, and the new drama, on the model of the French, introduced almost at once on the return of Charles II. and his courtiers from the Continent. The distinction between tragedy and comedy was then first substantially recognised: the former confined to heroic events and language, the latter to those of ordinary life. But tragedy, subjected to foreign rules, ceased gradually to flourish; and has never recovered itself. Comedy, on the other hand, obtained possession of the national taste and stage; and although the charm of poetry and romantic adventure, which had belonged to the old drama under either name, was denied to the modern comedy, it soon attained a high degree of excellence as well as popularity. The last comedies in verse were written shortly after the Restoration; since which time, with the exception of a few isolated attempts to revive the older form, it has been entirely framed on the French model. The main element of a modern comedy is satire; but it admits of a subdivision into comedy of intrigue and comedy of manners—the former being chiefly directed to the development of a plot, the latter to the delineation of manners; although these qualities ought, properly speaking, to be united to constitute a good play. The most distinguished of our dramatic writers in the former line are, amongst many, Congreve, Vanbrugh, Farquhar, Colman, Sheridan: in the latter, the writings of Shadwell and Foote, perhaps, afford the most remarkable instances of that less popular form of comedy which almost neglects the interest of plot, and confines itself to a satirical representation of prevailing vices and follies. (*Edinburgh Review*, vol. xxxviii.; *Prolegomena to Malone and Boswell's Shakspeare*; Hazlitt's *Lectures*; Coleridge's *Remains*; Collier, *History of English Dramatic Poetry*.)

German Drama.—The modern German drama is founded on the old English model; and, although the last in order of time, has risen to a high degree of excellence, the stage in Germany having been more recently national

DRAWBACK

and popular than in other European countries. While France, England, and Spain have to look back two hundred years for those names which form the glory of their dramatic literature, Lessing, Schiller, and Goethe are writers only of the past century.

Dramaturgy (Gr. *δραματουργία*). The science or art of dramatic poetry and representation; a word used by German writers.

Drapery (Fr. *drap, cloth*). In Painting or Sculpture, the clothing applied to the human figure is known by the name of *drapery*.

Drastic Medicines (Gr. *δραστικός, effective*). A term chiefly applied to purgatives and some other remedies which are rapid and powerful in their operation.

Draught of Water. The depth of the lowest point of the ship: as the keel is seldom exactly horizontal, the draught of water is taken forward and aft. A ship of the largest size draws nearly thirty feet.

Draughts. A game of great antiquity. An ancient papyrus, preserved in the Museum of Antiquities at Leyden, represents a man playing this game alone; but it is now always played by two persons on a board marked as for chess, with black and white pieces respectively. As these pieces were intended to represent a combat between two armies, they were called by the Romans *militie, soldiers, hostes, enemies*, and *latrunculi, robbers*. Among the Greeks the game was known by the name *παισιον*. Herodotus (i. 94) distinguished it from *κύβοι*, or the game of dice, which were, however, subsequently combined with the former, which was thus converted into a game of chance like our BACKGAMMON.

'A move at chess or similar game was formerly known by this name [draught], whence the game of draughts, or moves with separate pieces.' (Wedgwood, *Dictionary of English Etymology*, s.v.)

Drawback. In Political Economy. When a duty is laid on an article produced in a country that is suitable for the foreign market, it is usual, on its being entered for exportation, to remit or pay back the duty to the exporter; and hence the technical phrase *drawback*. The policy of a measure of this sort is, in most cases, obvious. It is rarely for the public advantage to impose a duty on an article about to be exported: the inevitable effect of such duty is, by proportionally increasing the price of the article, to lessen the foreign demand for it; and its probable effect is, in most instances, entirely to exclude it from the foreign markets. Except in a few rare cases, one country has seldom so great an advantage over others in the production of commodities as would justify the imposition of a duty on their exportation, without incurring an extreme risk of making them be supplied from some other quarter. This, however, is a result to be deprecated in every point of view. And hence in every case in which the exporting country has no ascertained or decided superiority over others in the production of commodities on which duties are laid at home,

DRAWBRIDGE

there can be no question as to the expediency of drawbacks. These must not, however, exceed the amount of duty charged; for when they do this, the excess becomes, in fact, a bounty.

Some few articles on which a customs duty is levied are not privileged with drawback on exportation. This is especially the case with corn under the existing duty of one shilling the quarter. The charge is a landing, not a bonding duty. Hence, while such a charge raises the price of all corn sold by the amount of duty levied, it prevents the country from becoming an entrepôt of grain for the rest of the world.

Drawbridge. A bridge erected upon a line of canal or on the approach to a fortification, so that it may be opened whenever it may be desirable to interrupt the communication, either for the purpose of allowing the passage of boats upon the canal, or for the sake of hindering the passage to the interior of the fortification. The same kind of bridge is also largely employed for the service of docks, or other places where the necessities of the traffic are such as to require that the levels of the roadway, over the bridges, should not interfere with those required for the waterway. From the necessities of the case it follows that there must be several varieties of these structures, such as the *lifting*, the *turning*, the *bascule*, or the *rolling* bridges.

The *lifting* bridges are erected when the boats are required to traverse the canal at the level of the roadway, or so near to it as to render it impossible to raise the latter sufficiently to allow them to pass under. If they are not made with a counterpoise to the weight of the platform, the machinery for hoisting them must be calculated so as to allow it to overcome the dead weight. Bridges of this kind are common on the Dutch canals, but they present the inconvenience of requiring that the passage way should be interrupted whenever the bridge is opened; and they also need a large framework to support the upper structure when raised; the roadway moreover hinders the ease of the manœuvres of sailing barges. For fortifications, this kind of drawbridge is commonly used, the roadway forming the gate when the bridge is removed; and the chains are usually made to serve as counterpoises upon the system invented by General Poncelet.

The *turning* bridges are used when it is necessary to substitute for the lifting bridges a structure which would allow the vessels to pass through them with all their standing gear in place, and they have the advantage of being placed at nearly the level of the water. The convenience of these bridges for dock service has produced their universal application in those situations where labour can be obtained easily, and where there is an absolute necessity for keeping the rigging of the ships in its original order. It is for this reason that the *bascule* bridges have been abandoned in the

DREAMS

docks where the navigation is very active, for they produce as much interference with the rigging of a ship as the lifting bridges would do. The *bascule* bridges, in fact, consist of a bridge turning upon a horizontal pivot, with a counterpoise rather in excess of the weight of the roadway; and they are, therefore, made to turn nearly of the precise width of the waterway. The foundations for the counterpoise must also be executed in the best hydraulic masonry; and the great gap thus left in the roadway when the bridge is raised constitutes a very serious objection to this kind of bridge. Many *bascule* bridges were introduced in the construction of the docks at Hull, and in those of Havre.

The *rolling* bridges have been introduced for the sake of accommodating the traffic upon the docks to the purpose of railways, and they may be described as consisting of a bridge made to move laterally upon a carriage until it has passed the junction of the line of rails, and then to pass inwards so as to leave the water-way clear. They require a considerable foundation, but they are very efficient, and offer no impediment to the navigation; one of the best examples is the bridge erected on the South Coast Railway over the river Arun.

DRAWBRIDGE. In Fortification, a movable bridge, used formerly in castles, and now in fortresses, allowing communication across the moat or ditch to be cut off or restored at will by those who hold its moving power.

Drawing. In the Fine Arts, the art of representing any object by means of lines circumscribing its boundaries. Drawing is of course the foundation of everything in art, including within it a knowledge of perspective, anatomy, and proportion, and when acquired giving, as Sir Joshua Reynolds observes, 'a proportionable power of drawing correctly what we imagine.' The human figure is the principal object, upon which a student should be first employed; for he who can correctly draw that will not be at a loss in representing anything else he may wish. Sir Joshua observes, that he who endeavours to copy nicely the figure before him, not only acquires a 'habit of exactness and precision, but is continually advancing in his knowledge of the human figure; and though he seems to superficial observers to make a slower progress, he will be found at last capable of adding (without running into capricious wildness) that grace and beauty which is necessary to be given to his more finished works, and which cannot be got by the moderns, as it was not acquired by the ancients, but by an attentive and well-compared study of the human form.'

In the great age of Greek art, drawing (*γυμναστική*) was a regular branch, and considered one of the most essential of the education of every gentleman. (Pliny xxxv. 36.)

Dreams (Gr. *Träume*). May be defined to be those trains of ideas which occupy the mind, or those imaginary transactions in which it is engaged, during sleep. The theory of

DREDGING MACHINE

dreams embraces two distinct classes of phenomena, *physical* and *psychological*: the former relate to the question as to how the body is affected in a state of sleep [SLEEP], how the body in that state affects the mind, and how this affection operates to the production of the phenomena of dreams; the latter, however intimately connected with, and probably dependent on, the former, comprehend an enquiry into the laws which regulate the train of ideas that occur during sleep, and the mode in which these laws operate, together with an examination of certain psychological appearances peculiar to that state. To both these classes of phenomena the attention of some of the most distinguished philosophers, both of ancient and of modern times, has been directed; but there is perhaps no subject on which opinions are more conflicting and unsatisfactory than the theory of dreams. Among a multitude of other *efficient* causes, dreams have been ascribed to direct impressions on the organs of sense during sleep—to the absence of real impressions on the senses—to a disordered state of the digestive organs—to a less restrained action of the mental faculties—to the influence of narcotics or stimulants—to the suspension of volition while the powers of sensation continue—and to the succession and unequal relaxation and cessation of the different senses at the commencement and during the time of sleep. From the remotest ages dreams have also been ascribed to supernatural agency. Dreaming is an operation of the human mind, which, like most others, man shares with the lower animals, who are observed frequently to dream.

Those who wish for comprehensive details on this subject may consult the writings of Aristotle, Lucretius, Democritus, &c.; and, among ourselves, of Locke, Newton, Hartly, Baxton, Beattie, and Steward. For the modern theories on the subject, Professor Bain's work on *The Senses and the Intellect* may be consulted with advantage.

Dredging Machine. A machine for clearing out or deepening the beds of navigable rivers, harbours, canals, &c., by the removal of deposited matters, which are scooped from the bottom in an endless chain of buckets, brought to the surface, and tilted into pontoons.

Dressing. A term applied to gunn, starch, and other articles used in stiffening or preparing silk, linen, and other fabrics.

Dressings. In Architecture, mouldings round doors, windows, and other openings on an elevation.

Drift. In Architecture, the horizontal force with which an arch tends to thrust out the piers laterally, is called the *drift*.

Drift. The newest accumulations of the upper tertiary period are sometimes thus named. *Drift* is a term best limited to material that has been recently moved by water, and thus includes various sands, marls and gravels, stratified and unstratified, fossiliferous and un-

DRIFTWAY

fossiliferous, not easily arranged. [GLACIAL DRIFT.]

All the so-called *drift beds* are of comparatively modern date, and they include the remains of animals that have recently inhabited the earth. Among these, however, are many remarkable for their large proportions, which have now become altogether extinct. Their remains are found in gravel and caverns, and are often so far covered up with newer deposits as to prove that there must have been great changes of the earth's surface since they were deposited. There has also been great change of climate. In these drift deposits, human remains have also been found, in sufficient abundance and in a sufficient number of places to render it certain that the human race was in existence contemporaneously with the great bears and hyenas, the elephants and rhinoceroses, and gigantic deer that roamed over the forests of parts of land now European before Europe was a continent. The drift is thus one of the most interesting of all deposits. [BOULDER CLAY and FLINT IMPLEMENTS.]

Drift. In Navigation, the angle which the line of a ship's motion makes with the meridian, when she is driven by the wind or waves and not governed by the helm. It also signifies the distance to which she is carried in a given time in that direction.

Drift Currents. These marine currents owe their origin to steady winds, blowing almost constantly towards one quarter, and with nearly equal velocity. In the Atlantic the trade winds cause such currents, but only between the latitudes within which these winds generally blow. The mean velocity of such currents is rarely more than ten miles per day, nor do they extend far below the surface.

In the Pacific, the drift currents produced first by the winds from the antarctic ice towards the equator, and afterwards those crossing the ocean in warm latitudes, are believed to produce the stream current running out from the Indian Ocean round the Cape of Good Hope and ultimately crossing the Atlantic.

Other drift currents less steady and constant are occasionally and seasonally produced by prevailing winds; but as it is only in the Pacific that they have space enough to attain steadiness and important magnitude, it is only in that ocean that they originate stream currents. It is generally considered that the water is elevated on the western side of the Pacific by their agency, and thus has some important influence in commencing the current which, crossing the Indian Ocean, and entering the Atlantic round the Cape of Good Hope, ultimately becomes the Gulf Stream. [GULF STREAM.] However this may be, there can be no doubt that the prevalent winds forming drift currents have some reference to stream currents.

Driftway. A small subterranean gallery, driven in advance of a tunnel; it is the first operation in tunnelling, and everything depends on its being correctly set out.

DRILL

Drill. In Agriculture, a machine for sowing agricultural seeds in rows; sometimes worked by the hand alone, and sometimes by the addition of a horse.

Drill. A small tool used by engineers and carpenters, &c., which consists of a metal stock that works by a handle, capable of being turned round easily in a fixed stock; the drilling and boring machines have the stock and drill fixed in the vertical direction, and the substance to be operated upon is placed upon a movable table.

Drill Husbandry. In Agriculture, the cultivation of arable land, by sowing the crops in rows; the advantage of which is, that it admits of destroying the weeds, and stirring the soil in the intervals between the lines of plants. This mode of cultivation requires some implements and machines not in use in the commoner kinds of farming; and being besides better adapted for some soils than for others, it is not in such universal use as the obvious advantages attending it would lead us to expect, but it is rapidly gaining ground.

Drip. In Architecture. The same as CORONA [which see].

Dripping Eaves. In Architecture, the lower edge of a roof is said to terminate with dripping eaves when they project over the line of the wall, and either allow the water which may fall on the roof to drip or drain off to the ground or to be caught in eaves, gutters nailed under them.

Driver, also called the **Spanker.** In Navigation. A quadrilateral sail hoisted on the mizen gaff, and extended at bottom by a boom. It is the principal 'fore-and-aft' sail; and is of great importance in an adverse wind.

Driving Notes. In Music, such notes as connect the last note of one bar with the first of the following one, so as to make only one note of both. They are also used in the middle of a measure, and when a note of one part terminates in the middle of the note of another; in this case it is called *binding* or *ligature*. [SYNCOPE.]

Driving Wheel. In Machinery, the term *driving wheel* is given to the wheel which communicates the motion to the pinion, or the second wheel deriving its motion from the first, which may either be a multiplying or diminishing wheel according to the necessities of the case.

Droits of Admiralty. The perquisites resulting chiefly from the seizure of the property of an enemy at the commencement of a war. These are attached to the office of lord high admiral, or to the crown when that office is vacant. They were originally vested in the sovereign, to enable him to provide for the expense of defending the realm, and clearing the seas of pirates; and their value and importance will be at once perceived from the following brief statement. In 1798, one ship which had been captured brought 55,000*l.*; in 1800, another brought 65,000*l.*; in 1804, one captured ship was worth 105,000*l.*; and in 1806, several taken at once netted 155,000*l.* During the French war, also, the Dutch ships at one seizure brought

DROPSY

1,030,000*l.*; the Spanish ships, 2,200,000*l.*; and so large were the sums made at one and the same moment in this rich field, that the crown one year, after paying many hundred thousands to captors, and large sums to different branches of the royal family, gave a million out of the residue to the public service. By the civil list introduced on the accession of William IV., it was arranged that all the droits of admiralty which might accrue during his reign should be paid into the exchequer for the benefit of the public service; and the civil list of her present majesty has made no alteration in that arrangement. [PRIZE MONEY.]

Dromatherium (Gr. *δρῆμα*, a race, and *θηρ*, beast). A genus of fossil mammalia which has been described by Dr. Emmons from the (probably triassic) coal-fields of North Carolina. It appears to have been insectivorous, and nearly allied to *Spalacotherium*. The dental formula is—

$$i. \frac{?}{6} c. \frac{?}{1-1} p. \frac{?-?}{3-3} m. \frac{?-?}{7-7} \text{ total } \frac{r}{28}$$

Dromedary. [CAMELUS.]

Drop Serene (Lat. *gutta-serena*). [AMAUROSIS.]

Drops. In Architecture, the frusta of cones in the Doric order, used under the triglyphs in the architrave below the *tænia*. They are also used in the under part of the mutuli, or modifications of the order. In the Grecian examples of this order, they are sometimes curved a little upwards on the profile.

Dropsy (Gr. *ὑδρῶσις*). An unnatural collection of watery fluid in any part of the body. When it takes place in the cellular membrane, it constitutes *anasarca*; when in the cavity of the abdomen, *ascites*; in the cavity of the cranium, *hydrocephalus*; in the scrotum, *hydrocele*; in the uterus, *hydrometra*; and in the chest, *hydrothorax*. Dropsy may arise from a variety of morbid actions, either of the secreting or absorbing vessels. When the fluid which lubricates the internal surfaces and cavities of the body is secreted in excessive quantity, or is not adequately removed by the absorbents, it may so accumulate as to constitute the various forms of this disease; it may therefore arise out of excessive as well as of defective action: it may also result from a variety of other causes connected with organic lesion or derangement, both vascular and nervous. Any cause obstructing the blood in its return from a part may produce dropsy, and thus we have it as a symptom of various forms of heart and lung disease. Dropsy is also a frequent concomitant of those organic changes in the kidneys known under the general title of *Bright's disease*. The treatment of dropsy will of course vary with the cause of the disease: it sometimes requires depletion, and at others tonics; and local accumulation of fluids is often susceptible of removal by remedies which stimulate the absorbents to increased action, or which excite the excretories of the intestines or promote the flow of urine. Dropsy is a common symptom

DROPSY

of a broken constitution and failure of the powers of life.

DROPSY. In Botany, a disease peculiar to succulent plants, arising from an excessive introduction of water into the system. It produces rapid rotteness, and can be stopped only by destroying all the parts affected, and exposing the plant to a very dry atmosphere.

Droseraceæ (Drosera, one of the genera). A natural order of Exogens, of the Berberal alliance, in which they are known by their regular symmetrical flowers, the stamens alternating with the petals or twice the number, and their parietal placentæ. These curious herbs are found in various parts of the world; the species of *Drosera* being remarkable for the glandular hairs which clothe their leaves, and which each secrete a drop of fluid at the point, so that the plants appear glistening with dew drops. These are called Sundews. *Dionæa muscipula*, called Venus' Fly-trap, whose curious fringed leaves clasp over and imprison any insects which may touch the bristles of their inner surface, also belongs to the order.

Drosometer (Gr. *σφόδος*, dew, and *μετρον*, measure). Any instrument for measuring the quantity of dew that collects on the surface of a body exposed to the open air during the night. [Dew.]

Drowning. When a person is submerged under water, suffocation ensues, not in consequence of the access of water to the windpipe or lungs, but merely from the exclusion of air; the mechanism of the glottis, or upper portion of the windpipe, being such as to prevent, by the spasmodic closure of the epiglottis, the entrance of more than a very trifling and accidental quantity of water. Under these circumstances, however, an attempt is made to inspire, which is followed by the reaction of expiration, and consequently a little air is thrown out, and the residuary quantity in the lungs still further diminished; access of oxygen to the blood is therefore effectually cut off, the aëration of the blood is prevented, and venous blood circulates in the arterial system, the right side of the heart becoming loaded with it, and the pulmonary vein returning it to the right cavities of that organ. The consequences of the non-aëration of the blood thus ensuing upon the vital functions is the suspension and rapid extinction of the latter; so that in the course of four or five minutes after the access of air has been cut off death ensues, although some of the organic functions may and do continue for a longer period. When therefore a person has been perfectly submerged in water for the space of five minutes, insensibility ensues, and the functions upon which life more immediately depends cannot be restored.

In consequence, however, of the struggles made by drowning persons, and of their chances of occasional gasps of air, and of the varying quantity of air which the lungs may contain, we must not despair of the possibility of resuscitation, even when the body has been for fifteen or twenty minutes in the water, although it must

DROWNING

be confessed that after four or five minutes' submersion the chances of recovery are very remote.

The state of alarm and agitation into which persons falling into the water, and who cannot swim, are thrown, and their ignorance in general of the means which should be resorted to upon such an emergency, as well as want of presence of mind to adopt them, lead to neglect of those obvious measures by which immediate dangers might be averted. They should know that the specific gravity of the human body when the lungs are filled with air is less than that of water, and that consequently the body has, under such circumstances, a natural tendency to float; and that if the head can then be so placed as to keep the mouth or even the nostrils above water, respiration may be continued. They should also remember that by a forced inspiration a much larger quantity of air may be drawn into and retained in the lungs than in a common or natural inspiration; and that therefore the blood will continue longer aërated, and consequently a longer period will elapse before a second attempt at inspiration need be made, and before insensibility or the cessation of the vital functions will ensue. If, for instance, while breathing as usual, we suddenly hold our breath, we shall find ourselves forced to make an inspiration in the course of from a quarter to half a minute; but if we previously make two or three forced respirations, so as to cleanse the lungs in the first instance of foul air, and then take a forced inspiration, we shall be able to hold breath for more than a minute, and sometimes even for two minutes. It is upon this principle, that skilful divers are enabled to remain under water for a period that sometimes appears almost incredible; and if the depth of water be considerable, and the air supplied from a diving bell, its degree of condensation or diminished bulk will of course enable a given volume to oxygenate the blood more effectually than the same volume at common atmospheric pressure.

Such, then, is an outline of the physiology of drowning; it naturally leads to the important question as to the most effective means of restoring suspended animation in such cases. It follows from what has been said, in the first place, that not a moment is to be lost in getting the body out of the water, and removing it with the utmost speed to any place where further means can be resorted to; and now air should be thrown into the lungs, and artificial respiration should be attempted with as little loss of time as possible, for till the blood has an opportunity of being aërated, the return of the vital functions is impossible. The body should also be immediately stripped of the wet clothes, which should be cut off or otherwise removed with the utmost speed; warm blankets should be at hand as wrappers, and warm towels for rubbing and drying the body. Artificial respiration, together with warmth and friction, carefully and moderately employed, are the first and most essential remedies. Much has been said of the advantage of

electricity in these cases; and, if possible, it should certainly be resorted to: slight shocks should be passed through the region of the diaphragm, the heart, and along the course of the spine; and various forms of the magneto-electric machine seem particularly well adapted to these purposes. The truth is, that the means to be adopted in all these cases are few and simple; but unless they are immediately at hand, and instantly available, they will fail, even under the most favourable circumstances. Yet, where even a glimmering of hope remains, they should, under any circumstances, be resorted to as speedily and completely as possible; for there are on record extraordinary cases of resuscitation when everything appeared to militate against a successful issue.

But in these cases it is not only important to know what to do, but also what to avoid. Nasal stimulants, such as ammonia, aromatic vinegar, and other pungent and volatile applications should be avoided: they can be of little use under the most favourable circumstances, and in the most judicious hands; and if unskillfully employed, may do infinite mischief. The warm-water bath is a bad substitute for warm air and friction; it interferes with the latter, and with the use of electricity, and places the body in constrained and unfavourable position. In these days it is scarcely necessary to point out the extreme absurdity of holding the body with the head downwards, to allow the water to run out by the mouth, or the still more dangerous use of tobacco, especially of the injection of tobacco smoke—means calculated to put the life of a healthy person in jeopardy, and every way suited to render all attempts at the restoration of suspended animation ineffectual.

Drugget. A coarse and flimsy woollen texture, chiefly used for covering carpets. It was formerly extensively employed as an article of clothing by the poorer classes, more especially of females; but this and similar fabrics are now almost wholly superseded by cotton goods, which induce greater cleanliness, and are less liable to retain infectious and contagious poisons.

Druids. The priests of the Celtic inhabitants of ancient Gaul and Britain. Some little information respecting them is derived from Julius Cæsar; also, Tacitus, Pliny, Lucan, and other authors, have also mentioned them. On those slender foundations very extensive superstructures have been raised by the imagination of English and French antiquaries. The classical name of Druid derived by the Latins from *druid*, an oak; but is more probably of Celtic origin. The doctrine of the Druids was not committed to writing, but retained by memory in the form of verses; of which the Welsh Triads are supposed, with some probability, to retain the form and vestiges. There appears to have been much of fraud and vulgar delusion mixed up in the religious rites which they practised. The gods whom they worshipped, according to classical writers, were Jupiter (Taraxis), Apollo (Belanus), Mars (Hesus),

and several others, whom they believed to be the same with personages of the Grecian mythology. The sacrifice of human victims is uniformly represented as a part of their worship. Their places of worship were chiefly consecrated groves, of one of which Lucan has given a fine description in the second book of his *Pharsalia*. The rock-altars, cromlechs, cisterns, and other relics of antiquity, which are scattered over the surface of parts of England and France, are attributed by antiquaries for the most part to the Druidical age. Claudius and other Roman emperors issued severe edicts against the Druids, but did not succeed in extirpating them. This was only effected by the general introduction of Christianity; and some suppose that the celebrated Culdees of Scotland and Ireland were converted Druids. (See the article 'Druids and Bards,' *Edinburgh Review*, July 1863.)

Drum. In Architecture, the upright part of a cupola above or below a dome; it is generally applied to the lower part. The same term is used to express the solid part, or vase, of the Corinthian and Composite capitals beneath the acanthus leaves. Sometimes also this word is used to express each course of stone that is used in the height of a column when it forms a complete section of the cylinder. In works upon machinery, a drum is made to express a hollow cylinder, fixed upon a shaft, for the purpose of driving another cylinder by a band; they may be of any size, multiplying or diminishing, and they may be crossed or plain drums, as the circumstances of the case may require. The advantage arising from the use of drums is, that the machinery to which they are applied works without noise, from the absence of any teeth-wheels or other gearing: the disadvantage lies in the gradual slackening of the *bands*, as the straps which communicate the motion are called.

Drum. In Music, an instrument of percussion, formed by stretching a piece of parchment over each end of a cylinder formed of thin wood, or over the top of a cauldron-shaped vessel of brass; the latter is hence called a *kettle drum*. The large drums which are beaten at each end are called *double drums*, and are used chiefly in military bands. Small drums, hanging by the side of the drummers, and beaten with great rapidity, are called *side drums*. Kettle drums are always used in pairs; one of which is tuned to the key-note, the other to the fifth of the key. The drum is principally used for military purposes, especially for exciting the soldiers under the fatigue of march or in battle. The drum is supposed to be an Eastern invention, and to have been brought into Europe by the Arabians, or perhaps the Moors. The kettle drum, the bass drum, and tambourine are common in the East.

Drum of the War. [See.]

Drummond's Light. The name given to the light produced by directing a stream of oxygen gas passing through the flame of alcohol upon a small ball of quick lime. The light

DRUPACEÆ

produced by burning lime in this manner is of extreme intensity, and Lt. Drummond, of the Engineers, while engaged in the trigonometrical survey of Ireland, suggested its use as a signal for the observation of distant stations. For this purpose the ball of lime, about a quarter of an inch in diameter, was placed in the focus of a parabolic mirror, the axis of which was directed to the point from which the observation was to be made; and such was the brilliancy of the light that it was sometimes distinctly seen, even in hazy weather, at a distance of upwards of sixty miles, when argand burners and other modes of illumination previously used were altogether ineffectual. But the use of this signal is found to be attended with some inconveniences, and the heliostat is now generally preferred in geodetical operations. (Lieut. Drummond's paper in the *Phil. Trans.* for 1826.)

Drupaceæ (Lat. *drupus*, its fruit being a *drupe*). One of the orders into which Lindley divides the *Rosaceæ*, and equivalent to a sub-order of that family in the estimation of some other botanists. Its peculiar features are polypetalous regular flowers, a solitary carpel whose style proceeds from the apex, and a drupaceous fruit. The Cherry, Peach, Plum, and Apricot furnish examples.

Drupe (Lat. *drupus*, *ripe and ready to fall*). In Botany, a one-celled, one or two seeded, superior indehiscent fruit, the outer coat of which is soft and fleshy, and separable from the inner or endocarp (stone), which is hard and bony; as in the Peach and Cherry.

Druses. A people inhabiting the mountains of Lebanon, and the coast from Gibail to Suide, and eastward as far as Baalbec. In religion they pass among the MARONITES [which see] for atheists. The great body of the people are certainly indifferent to any religious forms; but a certain sect, styling themselves Okkals, or Spiritualists, make extravagant claims to purity. The Druses are noted for their hospitality; but their resentment is easily roused, and this characteristic was artfully used by the Turkish authorities in fomenting the recent massacres of the Christians in Lebanon.

Dry (Sax. *drig*). In Painting, a term applied to a picture in which the outline is too strongly marked, and the colours of the objects do not unite with those by which they are surrounded. In Sculpture, it is used in speaking of a work wherein there is a want of luxuriousness and tenderness in the forms.

Dry Area. An enclosure constructed before a wall, sunk below the level of the-ground, for the purpose of intercepting the passage of the water from the outside of the building. It is usually formed by a retaining wall with cross buttresses so built as to maintain an efficient ventilation.

Dry Distillation. This term is applied to the distillation of substances *per se*, or without the addition of water; thus, if we put wood into a retort or other distillatory apparatus, and subject it to heat, it yields tar, vinegar,

DRYING OIL

water, and various gaseous and other matters, which are called the products of its *dry* or destructive distillation.

Dry Rot. A disease which attacks wood, rendering it brittle, and destroying the cohesion of its parts. It occurs among the timbers of ships, where it sometimes commits the most serious damage; and also in damp ill-ventilated houses. It is usually ascribed to the attacks of fungi, especially to such as *Polyporus hybridus*, *Thelephora putcana*, and *Merulius lachrymans*, whose filamentous spawn or thallus appears upon the surface, overspreading it like a tough thick skin of white leather; and there is no doubt of its being often connected with the appearance of such fungi. But dry rot is certainly, in some cases, to be traced to the presence of fungi of a more simple kind.

The destruction of timber by such plants is effected in part by the disintegration of the tubes of the wood, in consequence of the introduction between them of the fine filamentous spawn of the fungi, and in part by the dampness which is thus conveyed to the interior of the wood, where it soon produces decomposition. Dry rot, however, is not always caused in this manner. On the contrary, the term appears to be frequently applied to cases of spontaneous decomposition of timber without the presence of fungi, or when the appearance of the latter takes place long after the commencement of the disease.

When dry rot produced by fungi has once made its appearance, there is no means of arresting its progress without removing the whole of the diseased and neighbouring parts; and even then it will probably again break out, unless means can be taken to introduce a circulation of fresh air among the parts liable to the affection. For if timber is allowed to remain in a damp situation, and in the dark, it affords so favourable a nidus for fungi, that they are almost certain to vegetate upon it, unless some means have been previously taken to render the timber permanently unsuited to their growth. This end has been attained by a process called *kyanising*, which consists, so to speak, of pickling timber in a solution of corrosive sublimate. Various preparations of coal-tar, and its volatile oils, creosote, and similar products, are also effective in preventing dry rot.

Although dry rot generally fixes itself upon timber, it will also attack other matters. The paper hangings of rooms are occasionally overrun by it in houses which have been long shut up and neglected; the different appearances in these cases being produced by the special circumstances under which the fungus is developed, or by the species of fungus itself.

Dryads (Gr. *épudes*). In the Heathen Mythology, nymphs whom the ancients believed to inhabit the woods and groves.

Drying Oil. This term is generally applied to linseed and other oils which have been heated with oxide of lead; they are the bases of many paints and varnishes.

DRYOBALANOPS

Dryobalanops (Gr. *δρῦς*, an acorn, and *βάλανος*, oak). A tree of the *Dipteraceae* found in Sumatra, and known by its calyx having a cup-shaped tube and a five-cleft leafy limb, and by its three-valved capsular fruit being enclosed within the cup of the calyx. This tree, *D. Camphora*, furnishes a liquid known as camphor oil; while solid camphor is found in cavities of the wood.

Dryopithecus (Gr. *δρῦς*, and *πίθηκος*, ape). A genus of fossil long-armed apes, which was discovered at Sansan in the south of France, and of which evidences have since been discovered at Eppelsheim, in Germany. It has been conjectured from its dentition that it presented more affinity to the human race than any other monkey, living or fossil; but the conclusion is more probable that it was merely a species of Gibbon, allied to the *Hyllobates* which are now found in India.

Drysalter. A dealer in salted or dried meats, and in the materials used in pickling, salting, and preserving various kinds of food; hence drysalters usually sell a number of saline substances and miscellaneous drugs.

Drystove. A glazed structure for containing the plants of dry arid climates; such as the cactuses, mesembryanthemums, aloes, and other succulents of Africa.

Dual Number. In Grammar, the name given to that form of the verb and substantive by which, in the ancient Greek, Sanscrit, and Gothic, and the modern Lithuanian languages, two persons or things are denoted, in contradistinction to *plural*, which expresses an indefinite number of persons or things.

Dualism. A name given to those systems of philosophy which refer all existence to two ultimate principles. Dualism is pre-eminently an Iranian or Persian doctrine, which may be traced to the mythical phraseology of the Vedas on the daily struggle of light and darkness. Thus Ormuzd and Ahriman answer to the Indra and Vritra of the Vedic hymns. These names themselves recur in the Zoroastrian books. Vritra, the serpent or dragon, reappears as Verethra; and Vritrahan, the slayer of Vritra, as Verethragna. So Ahi, the snake, becomes Azi, and with the addition of dahaka, the foe, becomes the tyrant Asidahaka or Zohak, afterwards called also Anomainyus or Ahriman, the spirit of darkness. Among the Greeks, the Orphic poets made the ultimate principles of all things to be Water and Night; by others Æther and Erebus, Time and Necessity, are severally deemed worthy of this distinction. The ancient Greek and Roman mythology was evidently constructed on this principle. (Varro, *De Re Rustica*, i. 2.) In its more philosophic form, the dualistic theory was maintained among the ancients by Pythagoras and many of the Ionian school; among the moderns, chiefly by Descartes. [IONIC PHILOSOPHY; CARTESIAN PHILOSOPHY.]

In Theology, the doctrine of the two sovereigns of good and evil [MANICHRISM]

DUEL

is also dualistic; and the high Calvinistic theory may be said to be a species of dualism, viz. that all mankind are divided, in the eternal foreknowledge of God, and by His arbitrary decree, into two classes—the elect and reprobate.

Dubbing Out. A term used by plasterers to signify the system of bringing an uneven surface to a plane, or to carry out a series of small projections, by means of tiles, slate, plaster, or such like objects; they are added to the face of the brickwork beneath.

Ducat, Ducatoon. [MONEY.]

Duck. [ANAS.]

Duckbill. [ORNITHORHYNCHUS.]

Ductility (Lat. *ductilis*, easily led). This term is almost exclusively applied to that property of certain metals which enables them to be elongated or drawn out into wire. In this respect gold, silver, platinum, and iron, stand at the head of the list. A wire of platinum not exceeding a 30,000th of an inch diameter has been obtained by placing a fine wire of the metal in the axis of a larger wire of silver, then drawing the compound wire in the usual way, and afterwards dissolving off the silver by nitric acid, so as to leave the included platinum filament intact. A grain of gold may be drawn by the usual process into 500 feet of wire. Silver, for the purpose of embroidery, is commonly drawn into wire of 1-500th of an inch in thickness. [WIRE DRAWING.]

Ducts (Lat. *ductus*, from *duco*, I lead). Those membranous tubes in the internal anatomy of plants which have conical or rounded extremities; their sides being marked with transverse lines, or rings, bars, or dots, arranged spirally, and being incapable of unrolling.

Ductus Pneumaticus (Lat. *an air-channul*, from Gr. *πνεῦμα*, breath). The air-duct which communicates from the œsophagus to the air-bladder in fishes. It is the homologue of the *trachea* in the higher Vertebrata, which breathe air.

Dudley Rock. A name given to a limestone of the Wenlock series, situated near the base of the upper division of rocks of the typical Silurian district in England. The Dudley rock is the limestone on which Dudley castle is built, and which forms the fine escarpment at Wenlock Edge. It is the rock whence a very characteristic trilobite has been obtained, also known as the Dudley trilobite (*Calymene Blumenbachii*). Many corals, among which is the chain coral (*Catenipora escharoides*), are also characteristic.

Duel (Lat. *duellum*, a conflict between two individuals; in the original use of the Roman word, between two states). This word signified originally a trial by battle resorted to by two persons as a means of determining the guilt or innocence of a person charged with a crime, or of adjudicating a disputed right; but in more modern times it is used to signify a hostile meeting between two persons, arising from an affront given by one to the other, and for the purpose (as is said) of affording satisfaction to the person affronted.

DUEL

The practice of the duel, as a private mode, recognised only by custom, of deciding private differences, seems to be of comparatively recent date, and descends by no very direct transmission from the ancient appeal to the judicial combat as a final judgment in legal disputes. That it originated with the feudal system is abundantly clear, if it were only from the fact that in Russia, where that system was never known, the custom of the duel was unheard of, until introduced by foreign officers almost within the memory of the present generation. But it is certain that many antiquarian writers have confused together two very different institutions: the *appeal to arms*, as an alternative for the trial by ordeal or by compurgators, appointed by traditional usage from the earliest periods of Germanic history; and the *voluntary challenge or defiance*, resorted to for the purpose of clearing disputes involving the honour of gentlemen. This last custom was first elevated to the dignity of an established institution by Philip le Bel of France, whose edict regulating the public combat between nobles bears the date of 1308: the best comment on which may be found in the spirited and accurate representation, by Shakespeare, of the quarrel between Mowbray and Bolingbroke.

The fashion of the public duel seems never to have prevailed to any extent in England. Although the ancient *Judicium Dei* was so interwoven with our laws that, at a comparatively late era, the whole court of Common Pleas would occasionally adjourn in full term to Smithfield or Bankside, to see the 1 contested intricacies of a 'writ of right' brought fairly to issue in a match at singlestick; yet the stern necessity of washing out affronts in blood, whether in open or private quarrel, does not seem to have been strictly adhered to until the latter part of the reign of Queen Elizabeth. Then the imaginations of the young nobles of the court, heated with the favourite study of chivalry, readily adopted the sanguinary practice of foreign realms. At this period appeared the famous *Treatise of Honour* of Vincentio Saviolo—a fierce and punctilious Italian, a fencing master by profession, bred in the wars of Italy, and deeply versed in the science of the public duello, then a favourite theme of reminiscence, although no longer known in practice. This work, published in 1594—now little known save by the famous quarrel in Shakespeare's *As You Like It*, concerning the cut of the courtier's beard, which seems intended as a parody on some parts of it—appears to have been adopted by the gallants of the time as a standing book of reference in all cases of supposed insult. Saviolo resolves all quarrels into the lie—that is, he supposes the original insult to be followed, either expressly or impliedly, by a regular series of replies and retorts, until one or the other party is reduced to give the lie direct; which, like the phrase 'stupid youth' (*dummer junge*), in some German universities, was immediately followed by the appeal to arms.

That ordinary commotioner the lie,
The father of most quarrels in this climate,

appears to have been raised to this 'bad eminence' by Francis the First, the great guide of his day in matters of chivalry, who first gave it as his opinion, that the lie could under no circumstances be brooked by a man of honour. Attendoli holds that the virtue of the insult lies mainly in the word *lie*; and that any circumlocution, however plain, greatly deprives it of its effect. This, however, Saviolo stoutly denies; and maintains that an imputation on the veracity of a party, in whatever words it may be couched, is equally deserving of resentment. The lie, being a matter of so great importance, became the subject of much nice distinction; inasmuch that a note to Dr. Moore's *Essay on Duelling* informs us, that they enumerated thirty-two different ways of giving the lie in the latter part of the sixteenth century. Saviolo, however, contents himself with the division into the *lie direct* and *lie circumstantial*, each of which he subdivides into *general* and *special*; besides a fifth sort, which he calls *fictitious* or *sham lies*. These, he says, seem to have originated from the custom that he who receives the lie direct, or last retort, being of necessity the challenger, has the choice of weapons: to gain which advantage it was not unusual for one who sought a quarrel to address his enemy with, 'If you say I am a scoundrel, you are a liar;' by which means they supposed that the latter was put to the necessity of making a direct reply. In opposition to this notion, Vincentio shows divers honourable devices by which an ingenious duellist, when assailed in this manner, may retort on his adversary, so as to throw the burden of the last word on him. Paris de Puteo, a Neapolitan lawyer, is said to have practised chiefly in this branch of business, and to have answered cases on the point of honour put to him from all parts of Europe. Yet, however extravagant the folly of these early writers may seem on a matter of such serious nature, it must be confessed that, retaining as they did much of the old opinion, refined into a sentiment, respecting the immediate interposition of God in the judicial combat, the true point of honour was far safer in their hands than in the less scrupulous ones of the professed duellists of modern times.

In 1547, Henry II. of France issued an edict absolutely prohibiting the judicial or public combat. This decree was produced by the death of his favourite, La Chataigneraye, in consequence of wounds received in the lists in the presence of Henry himself. By a curious coincidence, the abolisher of one of the grand institutions of the feudal ages was destined, in his own person, to be the cause of the disuse of another: he was slain in a tournament, and that knightly exercise was no longer practised at courts after that melancholy event. The public duel survived some time longer in Italy. Its abolition in France was by no means followed by the good effects which the statesmen of those days probably anticipated from it. De-

DUEL

barred from public conflict, the gentlemen of France were at the same time freed from its manifold restraints; and private duels, conducted with a ferocity and sanguinary spirit hitherto unheard of, became very prevalent. The wars of religion, prosecuted with a degree of bitterness perhaps unexampled in the history of any nation, added public causes of dispute to those of an hereditary and personal nature. Even the ordinary laws of honour, which seem inseparable from the practice, were neglected. We find in Brantome, that there were duellists who prided themselves on the advantages which they had taken of their antagonists, and were not esteemed the less in society for having done so. Not only had individuals and families their quarrels; we are told that there were regiments in the same service, of which the officers were bound to fight one another whenever they met. The duellist seems to have usurped, with the fair sex, the attentions usually paid to the soldier. We have the testimony of Lord Herbert of Cherbury, himself a vain and cold-blooded quarreller, for the honour in which the ladies of France held the brave Balagny—an ordinary man, in a threadbare doublet and grey breeches, with neither figure, wit, nor fortune to recommend him; but whose testimonials consisted in the fact of his having killed eight or nine of his friends in single combat.

It was about the reign of Henry III. also, that the sanguinary custom of the seconds taking part in the quarrel of their principals seems first to have become established, a custom which only gradually wore out in the beginning of the last century. When such bloody practices were rife in all parts of France, we are scarcely tempted to doubt the extraordinary assertions we find in the writers of those days—that one hundred and twenty gentlemen were killed in duels, in a single French province, in six months; that in the reign of Henry IV. four thousand fell in two years; that this strange species of mania cost France more gentle blood than thirty years of civil war. Henry IV. issued edicts against duelling; Louis XIII. proceeded against it at one time with such severity, that we are told that wounded duellists were dragged at once from the field to the gibbet; but this unwarrantable violence, as usual in such cases, had no effect. The evil at length produced a remedy by its own excess. In the minority of Louis XIV. the duke de Nemours, a prince of the blood, fell, with two of his four seconds, in a quarrel with another grandee of the court. After this deplorable event, many noblemen and gentlemen of undoubted courage entered into a voluntary compact to abstain from duelling. Louis XIV., when of age, approved of their resolution, and seconded it by several edicts. To the honour of this prince, it should be remembered that during the whole of his life he laboured firmly and temperately to correct this abuse, and with no ordinary success. This he effected, not merely by the force of laws, but by exhibiting in his own demeanour, and encouraging in his

DUENNA

courtiers, that mixture of dignity with gentleness which most readily turns away wrath and repels insolent familiarity. One of his exponents, however, it must be admitted, seems to our modern ideas not very likely to attain the object proposed. This was the establishment of a court of chivalry—the members of which were the marshals of France—which was to decide on all questions in which a gentleman might conceive his honour to be involved. It is said that this singular sort of arbitration was at first very efficacious; although in Mercier's time (the reign of Louis XVI.) he tells us (as we might naturally suppose) that a person who should have resorted to the court to redress an insult would only have incurred ridicule, in addition to the disgrace of not personally resenting it. After much contest between the Court of Cassation and the inferior courts on the subject, slaying in duel, in France, is now held to be punishable as homicide, under various provisions of the Penal Code. A civil action lies on behalf of the friends of the slain man.

In England, the first attempt made to introduce legislative enactments in aid of the common law for the repressing of duels is said to have taken place in 1713; when, after the celebrated duel of Duke Hamilton and Lord Mohun, a bill for that purpose was brought into the Commons, but lost on the third reading. A provocation or challenge to fight is a high misdemeanour. In Scotland, as late (we believe) as the middle of the sixteenth century licenses for duelling were granted by the crown, and formed a source of revenue: death in a duel without license was murder. (*Pitcairn's Criminal Trials.*) The new codes of Bavaria and Prussia contain a number of provisions, with perhaps too much minuteness of distinction, against duels, challenges, &c. The common punishment is imprisonment for a shorter or longer term.

With regard to more recent times, it may be said that the practice of the duel is rapidly becoming obsolete: lingering most in those countries which adopted it latest. In France the period of the restored monarchy (1815–1848) was perhaps that of all her modern history in which duels were most rife; not only among the military, but among civilians; inasmuch that at one period almost all the personages engaged in the Parisian periodical press were accustomed to maintain their opinions by sword or pistol. But since 1848 they have greatly diminished. The same may be said of the more civilised part of the American Union. In this country, a heavy blow was aimed at duelling in the army by the new Articles of War of 1844, rendering it an offence punishable by cashiering. For some years duels, either military or civil, have been almost unheard of. Germany and the eastern parts of Europe, where the fashion penetrated later, seem now to afford the most numerous instances of it.

Duenna (Span. duenna). The chief lady in waiting on the queen of Spain. In a more general sense, it is applied to a person holding a

DUET

middle station between a governess and companion, and appointed to take charge of the junior female members of Spanish and Portuguese families.

Duet (Lat. duo, two). A piece of music composed for two performers, either vocal or instrumental.

Dugong or Dayong. The name of a herbivorous cetaceous animal, characterised by two large permanent incisive tusks in the upper jaw, and four molar teeth above and below, the grinding surface of which exhibits a rim of cement surrounding a slight excavated centre of ivory. The upper lip is beset with numerous strong bristles, and similar ones are found more sparingly scattered over the body. The anterior extremities are fin-like and without nails. The caudal fin is broad, and of a crescentic figure. One species (*Halicore indicus*, Cuv.) inhabits the seas of the Indian Archipelago. A second dugong has also been discovered in the Red Sea (*Halicore tabernaculum*, Rüppell). The fabled mermaid seems to have been founded on the dugong.

Duke (Lat. dux, leader or commander; the German herzog has the same meaning). The title of duke is said to have originated in the usages of the Byzantine Empire, where it was given to the military governors of provinces. Thence it was borrowed by the Franks; who adopted, in many respects, the titles and distinctions of the empire. Charlemagne is said to have suffered it to become obsolete, but

in 847. In course of time, according to the usual progress of feudal dignities, the title became hereditary. In Germany the dukes became the chief princes of the empire; this title being proper to all the secular electors and to most of the greater feudatories. In other countries their dignity became merely titular. In Italy and France, dukes form the second rank in the nobility, being inferior to princes; in England they form the first. The title was not known here until the reign of Edward III.; and the word *dux* is used by writers before that period as synonymous with *count* or *earl*. In the eleventh year of Edward III. the dignity of duke of Cornwall was bestowed on his eldest son, Edward the Black Prince. In the year 1351, Henry Plantagenet, earl of Lancaster (great-grandson of Henry III.), was created duke of Lancaster, furnishing the next instance of this dignity. In neither of these instances, nor in any subsequent one, according to Sir H. Nicholas (*Introd. to Peerage*, vol. i. p. lxxvii.), was the dignity thus created a dukedom by tenure: it has always remained a personal title only, and descendible according to the limitations of the patent.

Dulcamara (Lat. dulcis, sweet, and amarus, bitter). The common Woody Nightshade (*Solanum Dulcamara*), the stalk of which is used in medicine to furnish a decoction which is somewhat narcotic and diuretic, and has a bitter-sweet flavour. It has been recommended in chronic rheumatism, and as an alterative in some cutaneous cases, but is not depended upon.

DUNES

Dulcimer. A musical instrument, seemingly of the wind species, in use among the Jews. It is sometimes applied to a small instrument of stretched metallic wires, beaten with light hand hammers.

Dulcin. A saccharine matter isomeric with mannite.

Dulse. The Scottish name of various rose-coloured *Alga*, which are occasionally eaten for want of better fare. It is especially applied to *Rhodomenia palmata* and *Iridaea edulis*; while *Laurencia pinnatifida* is known as Pepper Dulse. These weeds are generally eaten raw, but when cooked have an unmistakable sea-twang.

Dumasine. An oily liquid obtained among other products, by distilling acetate of lime: its formula is $C_{10}H_8O$. Named after the celebrated French chemist, Dumas.

Dumbness or Aphonia (Gr. *speechlessness*). This term is generally applied to persons who are either born deaf, or become so in early infancy. The consequence of this is, that the organs of speech are never called into due action, their function being at first imitative in respect to sounds, and the numerous muscles of the tongue, glottis, &c., concerned in speech remain inactive; for persons who even in very early life become deaf are not rendered dumb, the organs of speech having been once called into activity, and having acquired their peculiar powers and consentaneous actions. Dumbness may also arise from injury to the lingual nerves, or from great general or local debility; in which case blisters, stimulants, tonics, and other remedies may be resorted to for the restoration of speech. It is remarkable that the loss of the tongue, and even of part of the palate, does not necessarily occasion dumbness: this has happened from disease, and among barbarous nations the tongue was occasionally extirpated; yet cases are on record showing that even under such circumstances speech was in some degree retained; and there is an account in the *Mémoires de l'Académie des Sciences* for 1718 of a girl who was born without a tongue, and yet acquired the faculty of speech. The case of Margaret Cutting, related in the *Phil. Trans.* (1742) by Dr. Parsons, may also be consulted in reference to this subject. These facts throw a curious light on the alleged miracle wrought on the confessors mutilated by Hunneric. (Newman's *Essay on Ecclesiastical Miracles*, prefixed to the translation of Fleury, Oxford 1842.)

Dumus (Lat.). In Botany, a low and much-branched shrub; hence the term *dumose*, applied to a low and bushy plant.

Dunes (A.-Sax. *low hills*). Hills of movable sand, which are met with along the sea-coast in various parts of Great Britain, Ireland, and the Continent. The mode of their formation and progress is exceedingly curious. In various districts the sea deposits on the beach a quantity of fine sand, which is carried forward by the wind till it meets with some obstruction in the shape of large stones, roots of trees, or other obstacles, when it gradually accumulates

DUNGIVEN CRYSTALS

into mounds or hillocks, whose general appearance, size, and distribution depend on those of the obstacles to which they owe their existence. When these mounds have attained a certain elevation, they are urged forward upon the land; for, as Cuvier observes, 'le même vent qui élève le sable du rivage sur la dune jette celui du sommet de la dune à son revers opposé.' The direction which they take depends chiefly on that of the wind; and their inroads upon the land are attended by the most destructive effects. One of the departments of France, the Landes, has been nearly overwhelmed by their progressive advance. The quantity of movable sand which the sea annually deposits on that coast has been estimated at upwards of 3,000,000 cubic feet, and its annual progress inland at about 72 feet. In that department the dunes advance in a north-easterly direction; and it has been calculated, that unless their progress be arrested, they will have reached Bordeaux in 1,500 years. During the violent hurricanes which frequently occur in these regions, the whole mass of sand of which the dunes are composed appears to be in agitation; and such is the rapidity with which they then advance, that entire villages, fields, and gardens are almost instantaneously engulfed, and the aspect of whole districts changed within four-and-twenty hours. The progress of the dunes, however, as already remarked, is in general slow and steady. Thus the town of Mimizan, after struggling for more than the fourth part of a century against their encroachments, is now almost buried beneath them; and such have been their destructive effects upon a village in Brittany, that nothing is visible of it except a small part of the church steeple. As will be easily imagined, the means of arresting the progress of the dunes forms an important enquiry. For this purpose various measures have been recommended; but by far the most efficient means hitherto adopted consists in planting close together, so as to form a line of defence against the sand, such trees and shrubs as are known to thrive in a barren soil. This process, wherever it has been tried, has been found not only to fix the dunes, but at the same time to form a simple and secure barrier against all further encroachment of the sand.

Dungiven Crystals. Yellow or smoky Rock Crystal found in detached crystals embedded in the soil at Finglen Mountain, near Dungiven, in Ireland.

Dunkers. A Christian sect which formed itself into a society under peculiar rules in Pennsylvania, in the year 1724. The origin of their name is unknown. They practise abstinence and mortification, under the idea that such austerities are meritorious in the sight of God, and effective, first in procuring their own salvation, and further in contributing to that of others. They form a society strictly connected within itself, and hold love feasts in which all assemble together; but their devotions and ordinary business are carried on in private, nor do they recognise a community of

DUODECIMAL

goods. They also deny the endlessness of future punishments; conceiving that there are periods of purgation, determined by the sabbath, sabbatical year, and year of jubilee, which are typical of them.

Dunnage. On Shipboard, the name applied to the loose wood or rubbish placed at the bottom of the hold to raise the cargo either for purposes of ballast, or to keep it dry.

Duodecimal (Lat. duodecim, *twelve*). Proceeding by twelves. The term is given to a rule or operation of arithmetic, by which the contents of any surface or solid are found by multiplying together its linear dimensions, expressed in feet, inches, and lines, and is consequently much used by artificers in finding the contents of their work. The rule is also called *cross-multiplication*, from the manner in which the operation is usually performed, which is as follows: Suppose it were required to find the superficial content of a plank 12 feet 9 $\frac{1}{2}$ inches long, and 3 feet 7 inches broad. Set down the two dimensions under each other, placing feet under feet, inches under inches, &c., and for the half inch put down its equivalent, 6 lines, as in the following example:—

$$\begin{array}{r} 12 \text{ } 9 \text{ } 6 \\ 3 \text{ } 7 \\ \hline 38 \text{ } 4 \text{ } 6 \\ 7 \text{ } 5 \text{ } 6\frac{1}{2} \\ \hline 45 \text{ } 10 \text{ } 0\frac{1}{2} \\ 12 \\ \hline 120\frac{1}{2} \end{array}$$

Now, since the feet are conceived to be units of measure, the inches are so many 12ths of unity, and the lines so many 12ths of a 12th, or 144th parts of unity. The units consequently form the first column, the 12ths the second, and the 144ths the third. Multiplying therefore the first line by 3 feet or 3 units, we get 38 feet, 4-12ths of a foot, and 6-144ths of a foot. Next, multiplying the upper line by 7-12ths, we get first the 6 lines or 6-144ths, multiplied by 7-12ths, equal to 42-1728ths, which is equal to 3 $\frac{1}{2}$ -144ths. Then the 9-12ths multiplied by the 7-12ths give 63-144ths, which added to the 3 $\frac{1}{2}$ make 66 $\frac{1}{2}$ -144ths, or 5-12ths and 6 $\frac{1}{2}$ -144ths; therefore 6 $\frac{1}{2}$ is placed in the third column, and the 5-12ths carried on. Lastly, the 12 units multiplied by the 7-12ths give 84-12ths, which added to the 5-12ths make 89-12ths, and this is equal to 7 units or feet and 5-12ths; consequently 7 is placed in the first column and 5 in the second. Adding the two products together, we get 45 feet, 10-12ths of a foot, and $\frac{1}{2}$ -144ths of a foot. But in square or superficial measure the 144th part of a foot is an inch; and 10-12ths = 120-144ths; consequently the result of the operation is 45 sq. ft. 120 $\frac{1}{2}$ sq. in.

The operation is itself much simpler than the description or explanation, which is found embarrassing to beginners; it would therefore, perhaps, be better to reject the rule altogether from elementary books of arithmetic; and, regarding the inches and lines as parts of a foot,

DUODECIMO

to perform the operation by the ordinary rule of *practica*.

Duodecimo. In Printing, a book is said to be in *duodecimo* (abbreviated 12mo.) when every sheet being six times folded makes twelve leaves or twenty-four pages.

Duodenum (Lat. duodeni, *twelve*). The commencement of the intestinal canal, forming a division, which in some animals is about as long as the breadth of twelve fingers. This term, introduced by the older anatomists, is still applied to that portion of the intestines, though the measure is generally inapplicable.

Duplicate Ratio. The ratio of the squares of two quantities, or the square of their ratio. Thus the ratio of a^2 to b^2 is the duplicate of the ratio of a to b . If there be three quantities in continued proportion, the first is to the third in the duplicate ratio of the first to the second: thus if a, b, c be continual proportionals, that is, if $a : b :: b : c$, then a is to c in the duplicate ratio of a to b .

Duplication of the Cube. A celebrated problem of the ancient Geometry. While a plague was desolating Athens, a deputation was sent to consult the oracle of Apollo at Delos, who returned for answer, that the plague would cease when they had doubled the altar of the god. The altar was cubical; consequently, the problem was to find the side of another cube of twice the solid contents. As this problem requires the solution of a cubic equation, it cannot be solved by elementary geometry; but Hippocrates of Chios reduced it to another; namely, the insertion of two mean proportionals between two given straight lines, a problem which several of the ancient geometers, particularly Archimedes, Eutocius, and Pappus, discovered methods of constructing by means of the higher curves. Among the modern geometers who have not disdained the same enquiry, are the illustrious names of Newton and Huygens. (Montucla, *Histoire des Mathématiques*.)

Dupper or Dubber. A globular short-necked vessel made of buffalo's hide, in which castor oil is imported from India. Each dupper holds about 80 lbs. of oil.

Dura Mater (Lat.). A thick membrane enveloping the brain and adhering to the inner surface of the cranium. [BRAIN.]

Duramen (Lat.). The fully formed central layers of the wood of Exogenous trees; what is called in common language the *heart wood*. It is the sapwood solidified by the introduction of various secretions into the interior of the cells or tubes of which such wood is composed.

Duress (Lat. *duritia*, *hardship*). In Law, is such constraint, either actual or by threats occasioning a reasonable fear, as will invalidate legal acts done by a party suffering it. Duress of imprisonment must be by illegal imprisonment. Duress per minas, by threats, is interpreted to mean such threats as occasion fear of life or limb.

Durio (Malay, *duryon*). The genus which produces the celebrated Durian fruit. The tree, which is called *D. sibethinus*, is cultivated

DUTCH SCHOOL

throughout the Malay peninsula and islands, where its fruit, during the time it is in season, forms the greater part of the food of the natives. The Durian is perfectly unique, combining the most delicious flavour with the most offensive odour. Both the flavour and odour are variously described; but it is said that when once the repugnance to the latter has been overcome, Europeans invariably become extremely fond of it. The unripe fruits are cooked as a vegetable. They are globular or oval, ten inches long, with a hard thick prickly rind, and a few seeds embedded in a firm pulp, which is the part eaten. The genus belongs to the *Sterculiaceae*.

Dutch Gold. Copper, brass, and bronze leaf is known under this name in commerce; it is largely used in Holland for ornamenting toys and paper.

Dutch Liquid. *Chloride of ethylene*. An oily liquid discovered in Holland in 1796, and obtained by the action of chlorine on *elephant gas*.

Dutch School. In Painting, this school, generally speaking, is founded on a faithful representation of nature, without attention to selection or refinement. The ideas are usually low, and the figures local and vulgar. Its merit lies in colouring and drawing with extreme fidelity what was before the eye of the artist. The pothouse, the workshop, or the drunken revels of unintellectual boors, furnished its principal subjects. Notwithstanding its deficiency in all that tends to raise the mind, it has acquired the utmost popularity in this country from its admirable imitation, and general perfection in execution. In the earlier centuries the Dutch school had nothing characteristic about it, but was historical and ecclesiastical, like the Italian and German schools; but after the Reformation and the ravages of the Iconoclasts in 1566, it lost the patronage of the church, and acquired a distinctive character. When the painters were no longer required to produce church decorations, they turned their skill to portraiture and to cabinet furniture; and produced the well-known *genre* pictures and landscapes for which Holland has now for two centuries been distinguished. A similar change from the force of example, and in proportion to the subversion of the old ecclesiastical influence, took place in Flanders and other parts of Belgium, but not to such an extent as to change the character of the Flemish school. To mention only a few: the greatest of the Dutch masters, though not the most characteristic, is Rembrandt van Rhyn, for portraits and figures: F. Bol, G. Flinck, F. Hals, and Vanderhelst were also excellent portrait painters; G. Dou, Terburg, Metsu, Mieris, and Netscher were admirable at conversation pieces; Brower, Ostade, and Jan Steen are as distinguished for the low subjects they painted as for the ability displayed in their execution; Ruydael, Hobbema, Cuyp, A. Vanderneer, Berchem, and A. Both are among the greatest of landscape painters; Ph. Wouwerman and Huchtenburg are unsurpassed as battle painters; W. Van

develde the younger and Bakhuisen excelled in marine pieces; and Willem Kalf, A. Van Utrecht, Van Huisum, and De Heem are unrivalled as painters of still-life and flowers. (Wornum's *Epochs of Painting*, 1864.)

Duties. In Political Economy. [CUSTOMS; EXCISE; TAXATION.]

Duty of an Engine. The mean amount of work that an engine is capable of effecting in a certain time. [DYNAM OR DYNAMICAL UNIT.]

Duumviri (Lat.). A general appellation, among the ancient Romans, given to any magistrates elected in pairs to perform any function or class of functions. The chief Duumviri were the Duumviri Sacrorum, to whom were intrusted the care and interpretation of the Sibylline books. The Duumviri Municipales had almost consular power in the municipal cities. The Duumviri Navales were officers appointed to man, equip, and command the Roman navy.

Dwarf Wall. In Architecture, a low wall, not so high as the story in a building in which it is used.

Dwarfing Trees. Dwarf trees may be produced in three different ways: by grafting on dwarf slow-growing stocks, as, for example, the pear on the quince; by planting in pots of small size filled with poor soil, by which the plant is stunted; and by causing a portion of the extremity of a branch to produce roots, and then cutting it off and planting it in a pot or box of poor soil. This last is the Chinese method, and is thus performed: The extremity of a branch two or three feet in length, in a fruit or flower bearing state—for example, the points of the branches of a fir-tree bearing cones, or of an elm bearing blossom buds—being fixed on, a ring of bark is taken off at the point where it is desired that the roots should be produced. The space thus laid bare is covered with a ball of clay, kept moist by being covered with moss which is occasionally watered. In the course of two or three months in some trees, and of a year or two in others, roots are protruded into the ball of clay. The branch may then be cut off below the part whence the roots have been protruded, and being planted in a pot of poor soil, and kept sparingly supplied with water, it will remain nearly in the same state for many years, producing leaves, and perhaps flowers, annually, but never shoots longer than a few lines.

Dyeing (A.-Sax. *deagan*). The object of this beautiful art is to fix certain colouring matters uniformly and permanently in the fibres of wool, silk, linen, cotton, and other substances. There are a few dyeing materials which impart their colour to different stuffs without any previous preparation, and these have been technically termed *substantive colours*. By far the greater number, however, of colouring materials only impart a fugitive tint under such circumstances, and require that the stuff to be dyed should undergo some previous preparation, in order to render the colour permanent; that is, capable of resisting the action of air, light, and water. The substance applied

with this intention is called a *bass* or *mordant*, and must possess an affinity for the fibre of the stuff on the one hand, and for the colouring materials on the other. The mordant often effects another important object, that of changing or exalting the colour at the same time that it fixes it. The principal mordants are alumina and oxide of iron, and these are usually applied in the state of acetates. As an instance, we may mention the mode of dyeing calico by means of *madder*, a decoction of which, if applied to the unprepared goods, would only give them a dirty red tinge, neither agreeable nor permanent. If the calico be previously passed through a weak solution of acetate of alumina, and then dried at a high temperature, and afterwards washed, a portion of the alumina is retained in combination with the fibre of the calico; and when thus prepared and submitted to the action of a hot decoction of madder, and again washed, it comes out a fine red, which is fixed in consequence of the attraction of the alumina for the peculiar principle which gives colour to the madder. If the mordant be oxide of iron instead of alumina, the colour which is then produced is purple; and various shades and colours are obtained by mixing mordants, by using more or less of them, and by applying the coloured solutions in various states of concentration. Sometimes articles are dyed by a similar precipitation of coloured metallic oxides in the fibre; thus yellow is obtained by passing cloth impregnated with acetate of lead through a solution of chromate of potash; a double decomposition ensues, and yellow chromate of lead is precipitated in and combined with the vegetable or animal fibre. Blues are produced by passing the goods previously mordanted with iron through an acidulated solution of ferrocyanide of potassium; these are generally called *chemical colours*, though not in fact more so than the others. Scarlet is produced by the colouring matter either of the cochineal or of the lac insect, and fixed by oxide of tin, and alumina, and heightened by the action of tartar.

The chemical principles of the art of *calico printing* are the same as those of dyeing, but the details are more difficult and complicated; and in consequence of the combination of a great variety of colours upon the same ground, the process is sometimes extremely refined and intricate; so that a rich, varied, and pleasing pattern, thus effectively produced, may be considered as a triumph of practical skill over theoretical difficulties, which is scarcely rivalled, and certainly not excelled, in any other of the arts. It is obvious that calico printing is in the abstract a topical dyeing; and much discrimination and taste are requisite in the contrivance of the pattern, its general design, and the colours in which it is exhibited. In this art the mordants, and sometimes the colours, are applied either by *blocks*, upon which the pattern is designed in relief, or by *copper plates*, which are engraved, or by *cylinders* or rollers. If the aluminous mordant be printed by one

block and the iron mordant by another, and a mixture of the two by a third, and the piece thus prepared be then passed through a madder bath, and properly cleansed and bleached, the colour will only adhere to the mordanted places, and it will be red where the aluminous mordant only has been applied, purple with the mixed mordant, and black with the iron; if the same three mordants be used with a decoction of quercitron bark, the resulting colours will be yellow, olive, and brown; and in this way a great variety of colours may be produced. Sometimes copperplate and block printing are combined; a fine running pattern being printed by the plate or cylinder over the whole surface, which serves as a groundwork, and upon which other figures are printed by blocks. Sometimes the mordant and colour are both applied at once by means of a block, and rendered fixed and permanent by exposing the goods for some time to steam. Some beautiful effects are also produced by printing the pattern upon a mordanted ground with some substance which will resist the colour, and so produce a white pattern upon a coloured ground. The same effect is sometimes brought about by discharging the colour by the topical application of certain bleaching materials.

Dyke. The material filling up a wide gap or fissure in rocks. The fissure may have been caused by contraction or during elevation; but if filled up by foreign mineral matter, either distinctly igneous or metamorphic, it is called a *dyke*. A dyke differs from a *FAULT* in not involving a shifting of the opposite sides of the crevice. The material filling up dykes is often crystalline and porphyritic. In Cornwall such a belt is called an *elvan*, and is often hard, compact, and of some thickness. Elsewhere the dyke will be greenstone, or ancient lava, or quartz rock. The porphyritic dykes in mining districts generally produce a marked influence on the value of the mineral veins. They more frequently injure than improve the vein, and if rich are generally valuable for a different metal than the one mixed in the adjacent country.

Dynaclinometer (a word coined from Gr. *dynamis*, power; *aktis*, a sunbeam; *μέτρον*, measure). An instrument for measuring the intensity of the photogenic (light-producing) rays, and computing the power of object-glasses. It is described by Mr. Claudet in the *Philosophical Magazine* for June 1851.

Dynam or **Dynamical Unit.** For the purpose of measuring or comparing the moving power of machines, or the useful effect produced by the exertion of animal force applied in different ways, it is necessary to adopt some standard, or unit of force, and for convenience of explanation it is desirable that the unit should be designated by an appropriate name. When the steam engine came into use, the work accomplished by it in a given time was naturally compared with that of the moving power which it most frequently superseded; hence the term *horse-power*, which was originally used by Watt

to denote, in a rough way, the force developed by a horse of average strength drawing a load during twenty-four hours without intermission. Watt subsequently gave a definite signification to the term, by defining it to be the force which suffices to raise a weight of 32,000 lbs. avoirdupois to the height of one foot in one second of time. O. Dupin, in his *Géométrie des Arts et Métiers et des Beaux-Arts*, proposed the term *dyname* to denote the unit of moving force, represented by one cubic metre of distilled water at its maximum density raised to the height of one metre in an astronomical day. Dr. Whewell, in his *Mechanics of Engineering*, recommended the adoption of the English synonym, *dynam*, to represent the effect equivalent to a weight of one pound raised to the height of one foot in a second. The terms *efficiency* and *duty* are frequently employed in a similar sense.

Dynameter. In Optics, an instrument for measuring the magnifying power of a telescope. The magnifying power is the ratio of the solar focal distance of the object-glass to the focal distance of the eye-piece considered as a single lens; and this ratio being the same as the ratio of the diameter of the aperture of the telescope to the diameter of its image or disc formed at the solar focus, and seen through the eye-piece, the object of the instrument is to measure the exact diameter of this image, which can be either projected on mother-of-pearl or measured by optical means. Ramsden proposed for this purpose the double-image dynameter [*MICROMETER*], an instrument formed by dividing the eye-lens of a positive eye-piece into two equal parts, and mounting them so that the divided edges are made, by means of a fine screw-apparatus, to slide along each other. Each semi-lens thus gives a separate image; and the distance of the two centres, measured by the revolutions of the screw, when the borders of the two images are brought exactly into contact, gives the distance of the centres of the images, or the diameter of one of them.

Dynamics (Gr. *dynamis*, force or power). This word, which signifies literally the doctrine of force or power, is the name given to that part of Mechanics in which motion is contemplated in connection with the forces of which this motion is the effect. It differs in the last respect from *kinematics*, which is the science of pure motion or change of position irrespective of its cause. Theoretical dynamics is a pure science based upon axioms of its own, which, though suggested by experience, are by a process of thought rendered sufficiently general to embrace the laws of natural phenomena. The primary conceptions of dynamics are *space*, *matter*, *time*, and *velocity*. Each of these heterogeneous magnitudes is susceptible of measurement or comparison with an arbitrarily chosen unit-magnitude of its own kind, and thus the science of dynamics becomes based upon that of pure *number*. It is customary in the systematic treatment of the subject to ascend from the dynamics of a single *particle* to that

DYNAMICS

of a system of particles, or a *body*. In virtue of the law of inertia each particle or mass-element is assumed to be incapable of altering its own condition, whether that be one of rest or of motion; and hence every alteration in the direction or velocity of the motion of a particle is ascribed to the action of *force*, of which latter indeed the alteration of velocity which takes place in the unit of time is considered as a measure. Calling x the distance described by a particle during the time t , its velocity at the end of that time will be expressed by

$$v = \frac{dx}{dt}, \text{ and the force acting upon it by}$$

$$f = \frac{d^2x}{dt^2}, \text{ provided it contains the unit quantity of matter. If, on the other hand, its mass}$$

be m , then the *moving force* F , as distinguished from the accelerating force f , will be expressed by

$$F = mf = m \frac{d^2x}{dt^2}.$$

Such are the relations between the elementary conceptions of dynamics. The manner in which they are applied to the problem of the determination of the motion of a system of particles may, to some extent, be understood by a reference to the article D'ALMBERT'S PRINCIPLES, but cannot, of course, be adequately explained here.

The science of dynamics is wholly of modern growth, and its foundations were laid by the celebrated Galileo. Before him no one had considered the forces which act on bodies, excepting in the case of equilibrium; and although the acceleration of falling bodies, and the curvilinear motion of projectiles, had been attributed to the constant action of terrestrial gravity, no one had yet succeeded in determining the laws of these common phenomena. Galileo first made this important step in advance, and thereby opened a new and boundless field for the progress of mechanics. Huygens added to Galileo's theory of the acceleration of falling bodies the theories of the motion of pendulums and of centrifugal forces, and thus prepared the way for the great discovery of universal gravitation. In the hands of Newton mechanics became a new science; and the discovery of the infinitesimal calculus at length enabled geometers to express all the laws and circumstances of the motion of bodies by analytical equations. The investigation of the forces which produce the phenomena of the material world, or of the mutual action of the different parts of matter on each other, now forms indeed one of the principal objects of mathematical studies. The best systematic treatises on dynamics are to be found in Lagrange's *Mécanique Analytique*, and Poisson's *Traité de Mécanique*. Besides these there are several excellent elementary treatises on the subject. Mr. Cayley's report on the 'Recent Progress of Theoretical Dynamics' (British Association 1857) may also be mentioned as a valuable work of reference.

DYSPEPSIA

Dynamometer (Gr. *δύναμις*, and *μέτρον*, a measure). An instrument to ascertain the force exercised by a steam engine, or any other motive power, which consists of a series of springs or levers, that are made to act by the force of the engine disconnected with any other machinery. General Morin invented the dynamometer that is now generally used for the purpose of measuring the duty of engines, water-wheels, windmills, or horse-engines.

Dynastides (Gr. *δυνάστης*, a master). A family of beetles, including the giants of the Coleopterous order. They are remarkably powerful insects, excavating burrows in the earth and also in putrescent timber, on which they principally feed.

Dynasty (Gr. *δυναστεία*, from *δυνάστης*, a lord or chieftain). A race or family of sovereigns in succession.

Dysæsthesia (Gr. *δυσαισθησία*, insensibility). Impaired sense of touch.

Dysentery (Gr. *δυσεντερία*; from *δυσ*, and *εντερία*, bowels). A disease of the bowels, endemic in many climates in the autumnal months, and frequently arising from marsh miasma, bad diet, exhaustion and fatigue: its symptoms are loss of appetite, sickness, pain about the bowels, and a frequent ineffectual desire to evacuate their contents, which when passed are mucous, fetid, and bloody, with small indurated lumps. It is often accompanied by intermittent and remittent fever, especially in hot and damp countries. In this country dysentery is generally a mild disorder, and not infectious; and is commonly cured by gentle aperients, such as castor oil, or salts and manna, to cleanse the bowels; and opiates to allay irritation. The chronic symptoms which remain are treated with mild tonics, especially vegetable bitters, such as infusion of calumba, cusparia, or cascarrilla. The contagious dysentery of camps, attended by remittent or typhoid fever, is an alarming and fatal disease; its treatment requires much consideration and skill, and consists in judiciously meeting the various symptoms as they arise. Diaphoretics and nauseants, especially ipecacuan, succeeded by tonics, are leading remedies; and the febrile symptoms must be treated according to their inflammatory or putrid tendency.

Dysodile (Gr. *δυσώδης*, fetid). A combustible mineral found in secondary limestone, at Melilli near Syracuse, in Sicily, of a yellowish or greenish-grey colour, either compact or in foliated masses which are composed of paper-like and flexible laminae, with impressions of fishes and plants. It is extremely fragile, emits an argillaceous odour when breathed on, burns with a crackling noise, giving off much flame and smoke, and a very fetid smell, whence has originated the name *Stercus Diaboli* or *Merda del Diavolo* which is given to it in Sicily. It is also found in France at Château Neuf, Dept. of the Rhône; Saint-Amand in Auvergne, and near Narbonne. It has also been discovered lately by Mr. Charles Gould in Tasmania.

Dyspepsia (Gr. *δυσπεψία*). Indigestion. This is a complaint from which few entirely

DYSPEPSIA

escape. It assumes an infinite variety of shapes and symptoms, and arises from many causes. In the higher ranks of society, and amongst the luxurious and opulent, it is a common consequence of over-eating, or of indulgence in not easily digestible or over-stimulating food, or of want of due exercise and general bodily and mental exertion. In others it results from mental anxiety and labour associated with a sedentary life; from the fatigues of business, or the influence of debilitating passions. In the lower orders it is the constant result of indulgence in spirituous liquors, combined in many instances with want of proper food, the means which ought to be applied to procuring it being disposed of in the gin shop.

The symptoms of dyspepsia vary, therefore, in the different grades of life. The epicure loses his relish for the most refined dishes, becomes bloated, plethoric, heavy and perhaps apoplectic; the lady of fashion suffers from headaches, flatulence, occasional giddiness, and dimness of sight; she becomes indolent, capricious, and full of fancies, or, as the old physicians used to say, she has the *vapours*; the studious man feels the intensity of his mind blunted, loses his appetite, or at least all enjoyment of meals, sleeps ill, and dreams much, gets whimsical and discontented with himself and his friends, and becomes a *hypochondriac*; the lower classes at first take their glass of gin or of rum because they find it a cheap stimulant, little thinking of the misery they are laying up for future years; this stimulation soon becomes habitual, and they not only feel miserable and heartbroken without it, but the single glass soon loses its efficacy, and the dose must be gradually increased till they degenerate into regular tipplers, whose aspect may be daily and hourly studied in those dens of iniquity, the gin shops of London, where it is curious and instructive, but humiliating and alarming, to witness the various grades of mental and bodily disease in men, women, and even children.

Complicated as are the symptoms of dyspepsia, and numerous as are the remedies and modes of treatment proposed for its relief or cure, they really resolve themselves into a few simple rules. In the majority of cases, *abstinence* is the first and most essential step: the epicure must abstain from the luxuries of the table, eat and drink with moderation, rise betimes, and use due exercise; the woman of fashion must revert to regular hours, that is, the night and the day must be employed as intended by nature, and not in inverted order; the philosopher and the scholar must occasionally, and often frequently and assiduously, divest themselves of their mental labours, and resort to amusements and occupations of a more trivial character. Those among the lower orders who have once acquired the habit of dram drinking are incurable; for such is the depression of mind and body, and such the gnawing

DYSURIA

restlessness which a want of the accustomed stimulus occasions, that without it they become miserable and inconsolable, and usually fall a sacrifice to mental or bodily disease, or to both combined: here, therefore, prevention is the only cure. The medical treatment of dyspepsia generally resolves itself into that of such of its particular symptoms or consequences as are most prominent; the inactivity of the bowels is to be opposed by proper aperients properly administered; the debilitated stomach to be strengthened by mild tonics, antacids, and stimulants. The mental symptoms often yield to the same treatment, and often require local depletion, or diffusible stimulants, such as ammonia and ether; and lastly, change of air, of scene, and of occupation are often indispensable, under which head sea-bathing and courses of mineral waters may be included. The above observations are of course inapplicable to all cases of dyspepsia resulting from structural disease, which, though often an effect, is also a frequent cause of symptoms of indigestion; indeed, such are the sympathies of the stomach that it is apt to be affected by any aberration from health.

Dysphagia (Gr. *δυσ*, and *φαγεῖν*, to eat). Difficulty of swallowing. Paralysis, stricture of the œsophagus, enlarged tonsils, relaxed uvula, a debilitated state of the muscular coat of the pharynx and œsophagus, spasm of the organs concerned in deglutition, and inflammation, are among some of the leading causes which occasion difficulty of swallowing; it is also an attendant upon hysteria, hypochondriasis, tetanus, trismus, and hydrophobia. The treatment will depend upon the prevailing cause, and is noticed under other articles.

Dyspnoea (Gr. *δύσπνοια*). Difficulty of breathing. This is generally a symptomatic affection, and commonly attends upon various morbid affections of the lungs, heart, &c. Effusion of fluid into the pleural or pericardial sacs is a common cause of the symptoms during the progress of many forms of dropsy and other diseases. It occasionally happens that persons in full health are seized with an attack of difficulty of respiration; where this occurs in nervous irritable habits, it generally goes off by perfect quiet, with the help of a little ether or ammonia; if in full habits, bleeding is sometimes requisite. Persons who are subject to these attacks should keep themselves as quiet and tranquil in body and mind as possible, and should avoid excess of food and wine, and even all stimulating diet. A recumbent posture, and sudden change of air—as going out of a warm into a cold room, or into the open air—will often relieve an accidental attack of dyspnoea.

Dysuria (Gr. *δυσουρία*). Dysury. Difficulty in voiding the urine. A common symptom in cases of gravel, inflammation of the urinary organs, spasm, and stricture. The nature of the relief must depend upon the exciting cause.

E

E. The fifth letter in the Hebrew alphabet and in those derived from it. In the Latin language it is often interchanged with *t* and *c*, and in the Greek with *α*, *ο*, and occasionally *υ*. In most languages *e* admits of great variety in its pronunciation, and, in French and English particularly, surpasses every other letter of the alphabet in this quality: as a Latin numeral *E* signifies 250—

E quoque ducentos et quinquaginta tenebit.

E. In Music, a note of the scale, corresponding to the *mi* of the French and Italians.

Eagle (Fr. *aigle*; Lat. *aquila*). In Heraldry, a bearing of frequent occurrence, and particularly assumed by sovereigns as the emblem of empire, from having been borne on the legionary standard of the ancient Romans. The eagle of Russia is *or*, with two heads displayed, sable, each ducally crowned of the field; the whole imperially crowned, beaked, and membered, gules. The eagle of Austria is also displayed with two heads; the Prussian eagle has on only. The Americans have adopted an eagle of a peculiar species belonging to their continent as the device of the Union, which is impressed on their gold coins.

EAGLE. In History, the symbol of royalty, as being, according to Philostratus, the king of birds. The eagle was borne as a standard by many nations of antiquity. The first who assumed it, according to Xenophon (*Anabasis* i. 10), were the Persians; it was used by the Romans at an early period of their history, but first adopted as their sole ensign in the consulate of C. Marius. (Pliny x. 4.) Before that time they had used as standards wolves, leopards, eagles, and other animals, indifferently. The Roman eagles were gold or silver figures in rilievo, about the size of a pigeon; and were borne on the tops of spears, with their wings displayed, and frequently with a thunderbolt in their talons. When the army marched, the eagle was always visible to the legions; and when it encamped, the eagle was always placed before the prætorium or tent of the general. The eagle on the summit of an ivory staff was also the symbol of the consular dignity. In modern times Napoleon caused the tricolor flag, which at the outbreak of the first French Revolution had become the standard of France, to be surmounted with an eagle; and thus constituted it the standard of the consular and imperial armies. From this circumstance, and from the almost unprecedented career of victory so long pursued by the French under this standard, the expression *eagles of Napoleon* is often used metaphorically to designate the *armies* under his command. After the battle of Waterloo, the eagle was superseded by France by the fleur-de-lys, the ancient emblem of the

Bourbon race. Eagles are frequently found on ancient coins and medals; especially on those of the Ptolemies of Egypt and the Seleucides of Syria. An eagle, with the word *consecratio*, indicates the apotheosis of an emperor.

EAGLE. In Ornithology. [*AQUILA*; *FALCONIDÆ*.]

Eagle, Black. A Prussian order of knighthood, founded in 1701; united with the Order of the Red Eagle, or Order of Sincerity, instituted by the margraves of Bayreuth.

Eagle Stone. [*ÆTITES*.]

Eagle Wood. The fragrant wood of *Alloxylon Agallochum*, used by the Asiatics for burning as incense. The Malayan name is *Agila*, whence the Portuguese name *Pao d'Agila*.

Eagre. A Norse word, which is used to express the sudden rise of the tide in a river, or estuary, commonly called *the bore*.

Ear (Ger. *ohr*; Lat. *auris*). The external ear is formed of a pliant cartilage covered by a thin skin, and having appropriate nerves and muscles; its various cavities and projections have received distinctive names from the anatomist. In the annexed diagram *a* represents the external ear, *b* the external meatus, *c* the

tympanum, *d* the malleus, *e* the incus, *f* the stapes, *g* the semicircular canals, and *h* the cochlea. The curved and irregular passage which leads to the inner ear is called the *meatus auditorius*, and in the adult is more than an inch in length; it is lined with a peculiar secretion called *cerumen*. The *tympanum* separates the external from the internal ear; it is closed by a membrane called the *membrana tympani* or *drum of the ear*, upon the inner surface of which a nerve called the *chorda tympani* ramifies, and to the centre of which is affixed the process of a little hammer-shaped bone, called the *malleus*, and which, together with the *incus*, the *os orbiculare*, and the *stapes*,

EAR SHELL

forms a chain of communication between the *tympanum* and the *fenestra ovalis*: these small bones are supplied with appropriate muscles. The *vestibule* is a small cavity in the petrous portion of the temporal bone, having a little spiral cavity called the *cochlea* connected with it, and three cylindrical cavities, or tubes, bent in a semicircular form, two of which are horizontal and one vertical. These cavities contain a liquid; and in them the auditory nerve, which proceeds from the fourth ventricle of the brain, ramifies and terminates. It is obvious that vibration of the tympanum, occasioned by undulations of the air, may be communicated through the bony chain above mentioned to the fluid in the vestibule, and thence to the acoustic nerve; but any further uses of this extraordinary and complicated mechanism are beyond our knowledge.

Shell. [HALIOTIDÆ.]

Trumpet or Hearing Trumpet.

An instrument for aiding defective hearing. The ordinary ear trumpet consists of a metal tube, usually of a conical shape, the wide end being turned towards the speaker to collect the waves of sound, and the narrow end terminating in a small tube, bent sideways so as to enter the ear of the deaf person. Various other instruments besides the trumpet are used for the same purpose. The *auricle* is a small scroll-shaped instrument which is worn in the ear, the expanded mouth only being visible. *Ear-cornets* are applied outside the ear, and held in their place by a slender steel spring, a bent tube entering the ear in this case, as in that of the common trumpet. Flexible tubes, made of India rubber covered with silk, and kept open by a spiral spring of wire, terminating at one end in a tube, which enters the ear, and in a cup or hollow hemisphere at the other, into which the speaker speaks, are found to be of great efficiency. *Sonifiers* are large bell-shaped instruments of metal, which are placed on a table, and turned towards the part of the room whence the sound proceeds, and the sound being collected at the bottom of the instrument is conveyed to the ear by a flexible tube. With respect to acoustic instruments in general, it does not appear that mathematical accuracy of figure is of much importance. Whatever prevents the dispersion of the undulating air, and directs it upon the tympanum, will partially assist hearing, though, of course, it is advantageous that as much as possible of the sound which enters the instrument should be reflected forward to the ear.

Small ropes fastened to cringles (loops) in the upper corners, and also to the leeches of sails, for the purpose of fixing the leeches of the sail to the yard. The first or head earings fix the corners of the sail permanently, the second being used only in reefing.

Earl (Norse, Jarl). This title denoted at first any person of noble race (Palgrave's *Rise of the English Commonwealth*); and there seem to have remained in popular language

EARNEST

traces of this ancient use of the name down to a late period. Afterwards some of the Anglo-Saxon earls were hereditary, and some were official governors of extensive districts. After the Conquest, the title of *earl* was used by the English to express the French title of *count* (in Latin *comes*): to which again the word *graf* (identical in origin with the English *reeve*) furnishes an equivalent in Germany. Hence the wife of an earl is still styled *countess*. In writings earlier than the age of Stephen, the Latin word *consul* is also used as synonymous with *earl*. It has been supposed (and the explanation is supported by Mr. Cruise, *On Dignities*, p. 17) that the dignity of an earl was originally annexed to the possession of a certain tract of land, and that there were three sorts of earldoms—one, when the dignity was annexed to the possession of a whole county with *jura regalia*, in which case the county was a county palatine, as Chester, Pembroke, and Durham; the second, where the earl had no possession of the county, and no advantage from it, but the third penny or third part of the sum arising from pleas in the county court; the third, where a tract of land was granted to hold as a county, *per servitium unius comitatus*. But this is an opinion open to controversy; and it may be doubted whether there are any settled principles as to the creation or descent of earldoms earlier than the reign of Edward III., when they were granted by letters patent to the earl and the heirs of his body. Earldoms, like baronies, gradually became converted from territorial to merely titular honours. These two were the only titles in the English peerage, until the creation of the duchy of Cornwall in the eleventh year of Edward III. (Nicolas's *Synopsis of the Peerage of England*.)

Earl Marshal of England. One of the great officers of state, who regulates ceremonies, takes cognisance of all matters relating to honour, arms, and pedigree, and superintends the proclamation of peace or war. The court of chivalry, *curia militaris* (now almost forgotten), was formerly under his jurisdiction: he is still at the head of the heralds' office, or college of arms. Camden, in his discourse concerning the office of earl marshal, alleges that it was first introduced in the reign of Richard II., who conferred it on Thomas Mowbray, earl of Nottingham, his predecessors having been styled only *marshals* of England. Various limitations have been made in the grants of this office from time to time; but it is now hereditary in the family of Howard, and enjoyed by its head, the duke of Norfolk.

Earnest (Lat. *arrhes*, Fr. *arrhes*). In Law, is a part of the subject of a contract, as money or goods, transferred, in order by such delivery to pass the property in the whole, or in some other way to confirm the contract. By the Statute of Frauds, 29 Ch. II. c. 3, no contract for sale of goods of the value of 10*l.* or more is good unless in writing, or unless such earnest be given or taken.

EARRINGS

(*Ger. Ohrring*). Ornaments worn by women, and sometimes by men, in all ages and countries. In the middle ages they were termed *Pendants* (which see).

Earth. In Architecture. [*Crossed*].

Earth (*Ger. Erde. Goth. airtha*, originally *airth*, *and land*). The name of the planet which inhabits. It is the third in order from the sun, its orbit embracing the orbits of Mercury and Venus, but being within the orbits of all the other planets. The earth is endowed with two principal motions; first, a motion of rotation about an axis passing through its centre; and secondly, a motion of revolution about the sun. It is the first of these motions which produces the phenomena of day and night, and the apparent diurnal revolution of the celestial bodies. The time in which the earth's rotation is performed is measured by the interval which elapses between two transits of the same fixed star over the meridian of any place; and this interval is always precisely the same. At all events, astronomers have proved that it cannot have varied so much as three times the thousandth part of a second since the date of the first astronomical observation, that is to say, during the last two thousand years. It is called the *sidereal day*, and forms a perfectly uniform measure of time. [*GYROSCOPE*].

The revolution of the earth round the sun is performed in an elliptic orbit, which lies all in one plane, and has the sun in one of the foci. The eccentricity of the orbit, or the distance of the foci from the centre, is 0.01679 parts of the mean distance of the earth from the sun; so that if we take the mean distance for unity, the greatest distance of the sun is 1.01679, and the least 0.98321. The mean distance is nearly 93 millions of miles. The motion of the earth in its orbit is not uniform; being most rapid when it is at its *perihelion*, or point nearest the sun, and slowest at its *aphelion*, or greatest distance from the sun. This inequality of the angular motion of the earth round the sun gives rise to an inequality in the lengths of the *solar day*, the name given to the interval of time between the successive transits of the sun over the same terrestrial meridian. Astronomers, with a view of obtaining a uniform measure of time, have recourse to a *mean solar day*, the length of which is equal to the mean or average of all the apparent solar days in a year. The time in which the earth performs a revolution in its orbit, with respect to the fixed stars, or points in absolute space, is 365.2563612 mean solar days, or 365d. 6h. 9m. 9.6s. This is called the *sidereal year*.

The plane in which the earth describes its orbit is called the plane of the *ecliptic*. The axis of the earth is not perpendicular to the plane of the ecliptic, but makes with it at the present time an angle of $66^{\circ} 32' 38.31''$; whence the *equator* of the earth is inclined to the ecliptic in an angle of $23^{\circ} 27' 24.69''$. This inclination, which is called the *obliquity of the ecliptic*, gives rise to the phenomena of the seasons, and to the varying inequality of day

EARTH

and night. In fact, as the two planes intersect always at the centre of the earth, it is evident that if while the earth is carried round its orbit, its axis of rotation remains always parallel to itself, the sun must rise above the equator during one half of the revolution, and fall below it during the other. Now this is what takes place: the earth's axis of rotation preserves very nearly its parallelism, or points without sensible deviation towards the same star during the whole year; and the sun in consequence at one period of the year is $23^{\circ} 27' 24.69''$ to the north of the equator, and at the opposite season of the year is precisely the same distance to the south of it. The straight line formed by the intersection of the planes of the equator and ecliptic does not preserve the same position on the ecliptic: it has a slow motion *westward*, or contrary to the order of the signs, and retreats at the rate of $50.1''$ annually; so that when the sun appears to return to the equator, the sidereal revolution has not been quite completed: there remains an arc of $50.1''$. The time in which the sun, or, to speak correctly, the earth, describes this arc is 20m. 19.9s.; consequently the periodical return of the seasons is shorter by 20m. 19.9s. than the true sidereal revolution of the earth round the sun. The revolution of the seasons forms what is called the *equinoctial* or *tropical year*; which, therefore, is equal to 365.2422414 mean solar days; or 365d. 5h. 48m. 49.7s.

The figure of the earth is that of an oblate spheroid of revolution, one of the equatorial diameters being also slightly longer than the other. The equatorial diameters are respectively 41,852,864 and 41,843,096 feet, and the polar diameter 41,707,796 feet. [*DAGERRA*]. Hence, supposing the earth to be a sphere, its whole surface would contain about 195,625,000 square miles.

The *mass* of the earth compared with that of the sun is nearly as 1 to 355,000. Its mean density, which has been ascertained by observing the effect of mountains in deflecting the plumb-line from the perpendicular [*Attraction of Mountains*], and by experiments on the attraction of leaden balls, is to that of water as 5.67 to 1. [*CAVENDISH EXPERIMENT*]. The centrifugal force at the equator is to that of gravity as .00346 to 1; and the force of gravity there is such that bodies fall through 16.1 feet in the first second of time. If the rotation of the earth were seventeen times more rapid, the centrifugal force at the equator would be just equal to the attractive force, and bodies would have no weight.

The interior of the earth is for the following reasons generally supposed to possess a high temperature:—

1. The form of the earth, nearly spherical, and flattened at the poles of rotation, together with the regular disposition of the materials about the centre in elliptic layers, proves that it must have originally existed in a fluid, if not an æriform state; so that the constituent molecules must have had free liberty to obey the forces

EARTH

arising from their mutual attraction and from the rotation of the whole mass, and arrange themselves in the position of equilibrium. But there is no other agent than heat to which we can attribute the fusion of such substances as compose the greater part of the exterior crust of the earth. 2. The phenomena of volcanoes, hot springs, and earthquakes, receive a very simple explanation on the hypothesis that the nucleus of the earth still remains in a state of fusion, and that the consolidation of the exterior crust still proceeds, though at an extremely slow rate. 3. The fact (which now appears to be fully established) that a sensible increase of temperature takes place as we descend from the surface (in deep mines for example), after passing the depth at which the influence of the solar heat ceases to be felt, furnishes a direct proof of a very high temperature in the interior of the earth. Much uncertainty exists as to the rate at which this increase takes place; but the mean result of a number of experiments made in the deep mines of Cornwall, and different parts of France and Germany, gives an increase of 1° of Fahrenheit's thermometer for every fifteen yards of vertical descent, after passing the stratum of constant temperature. Admitting this rate of increase, and supposing it to be continued to the centre, the intensity of heat at the centre will be expressed by $3,500^{\circ}$ of Wedgewood's pyrometer. The temperature of 100° of Wedgewood, which is sufficient to fuse the lavas and the igneous rocks, would be found at the depth of 125 miles; but M. Cordier, who, in the *Memoirs of the Royal Academy of Sciences of Paris* (volume for 1827), has collected a great number of facts relative to this subject, is of opinion that the phenomena warrant the conclusion that the mean thickness of the solid crust of the earth does not exceed 60 miles. Professor Hopkins, on the other hand, expresses an opinion, founded on the precession of the equinoxes, that the thickness of the solid crust is much greater.

In whatever manner the earth may have taken its existing form, there are abundant proofs that its surface has been the theatre of many great revolutions. The masses of sand and gravel, and beds of limestone composed of shells and corals, which are found in the interior of continents, and even to the summits of the highest mountains, plainly show that the present land was once immersed deep under the waters of the ocean. The remains of animals and plants belonging to tropical countries, found in the highest latitudes, indicate an entirely different disposition of climates from that which now exists. The appearances of the mineral strata, twisted, and dislocated, and broken asunder, also afford undeniable evidence that the changes which have taken place on the surface of the earth have not all been brought about by the silent action of the causes which we see in daily operation, but by the operation of some sudden and violent force.

EARTH. In Agriculture, earthenware is distinguished from soils by their being without or-

EARTHENWARE

ganised matter in their composition. Though scarcely any such earthenware is found on or near the ground's surface, yet the distinction is of use in speaking of soils. Thus we say a soil, the basis of which is earth, of sandstone, or of chalk, &c.

EARTH. In Chemistry, this term is applied to certain insoluble oxides of abundant occurrence in rocks and soils, such as silica and alumina. Lime, magnesia, baryta, and strontia have been called *alkaline earths*, their action on vegetable colours being similar to that of the alkalies.

Earth Currents. [**MAGNETISM, TERRESTRIAL.**]

Earth Warts. Various subterranean substances produced by plants. In England the name is given to the tuberous root of *Bunium flexuosum*, an umbelliferous plant; in Egypt to the round tuber of *Cyperus rotundus*, and other species of the same genus; in China to the subterranean pods of *Arachis hypogaea*, a leguminous plant; and in other countries to similar pods produced by the genera *Voandzeia*, *Amphicarpea*, &c.; or to the small tubers of *Cyperaceous* plants.

Earth Shine. [**MOON.**]

Earthenware. The art of fashioning clay into instruments of domestic use was one of the earliest and most widely diffused of those which the human race has cultivated. Even in the remotest periods, and before the use of metals, the custom prevailed of making vessels of clay, which seem to have been turned upon the wheel as well as baked. The Greek and the Roman form of civilisation produced objects of this description which are but the continuation of the traditions of the stone age; and the savages of the present day manufacture ornaments in the style of their ancestors.

Without endeavouring, however, to trace back the history of this art to the earliest period, it may suffice to mention that the Egyptians and Assyrians appear to have possessed it in considerable perfection; for the paintings on the Egyptian tombs show that the former were acquainted with the use of the potter's wheel; while the remains of pottery show that the Assyrians employed glazes similar to those used at the present day. The Greek earthenware, like all the other productions of that highly gifted race, was marked by an intimate knowledge of the effect of form and outline; and the later specimens of their ware contain illustrations of the other arts, and of the social habits of the times. In the beginning the Greek vases were of a pale yellow clay, with the figures painted in a dark reddish-brown colour; but at a later period the figures were painted by a black glaze, upon a pale or a red ground; the designs being of the most elaborate and beautiful character. The Romans appear to have extended the application of the art to the manufacture of all kinds of articles of domestic use, for the remains of their tile and pottery works are to be met with wherever they possessed the soil. Generally speaking, their ware is of a red colour, arising from the presence of a peroxide of iron in

EARTHQUAKES

the paste, and it bears a brilliant glass. The Moors appear to have taken up the art from the time of the destruction of the Roman empire, and to have introduced the brilliant colours which characterise their productions. From the Moors the Italians seem to have learnt the art of making their ware, which was perfectly manufactured in Majorca, and subsequently on the Italian mainland, at Gubbio, Urbino, &c. Giorgio, Andreoli, and Lucca della Robbia are the great masters of the art; they flourished about the end of the fifteenth and the beginning of the sixteenth centuries. The Gubbio wares were remarkable for their iridescent hue; the other specimens of the so-called Italian majolica are, however, principally remarkable for the purity of their design: for their mechanical execution was very deficient, and characterised an early period of art. The Limoges ware was also of the same kind, though the later productions of these artists were marked by an improvement in the style of handling colours, and to some extent for an improvement in the forms of the objects; but the great step taken by the French artists was the invention of the white glass by Bernard Palissy. The art of earthenware manufacture was preserved at the establishments of Rouen and Strasbourg, and to some extent in Paris itself; but about the beginning of the last century the Dutch succeeded in winning for their Delft ware a European reputation, which lasted until the latter end of the last century. Subsequently to that period the English have entered the field, and have far surpassed their rivals in the solidity and beauty of their wares. Wedgwood began the improvement upon the old Chelsea china; Chamberlain improved that of Worcester; Turner, that of Derby; while Spode, Copeland, Minton and others, have maintained the excellence of the British ware. The Prussians have of late made; and the Italians have; to the factory of the Capo di Monti ware; whilst there have been but few productions from the Spaniards, Portuguese, and Russians, who to be content to borrow their arts from their more energetic neighbours.

Earthquakes. Undulations produced in the external film or crust of the earth by force acting from within tending by a sudden explosion to rend asunder the surface; this result being prevented more or less completely by the elasticity of the matter lying above the seat of disturbance. The result is the production of a wave, which in its transmission along the surface originates the phenomena in question. [VOLCANOS.] Earthquakes are usually preceded by a general stillness in the air, and an unnatural agitation of the waters of the ocean and of lakes. The shock comes on with a deep rumbling noise like that of a carriage over a rough pavement, or with a tremendous explosion resembling a discharge of artillery or the bursting of a thunder cloud; sometimes heaving the ground perpendicularly upwards, and sometimes rolling it from side to side. The single

shocks of an earthquake seldom last longer than a minute, but they frequently follow one another at short intervals for a considerable length of time. During these shocks large chasms are made in the ground, from which sometimes smoke and flames, but more frequently stones and torrents of water, are discharged. In violent earthquakes, these chasms are sometimes so extensive as to overwhelm whole cities at once. In consequence of these shocks, also, whole islands are frequently sunk and new ones raised; the course of rivers is changed, and seas overflow the land, forming gulfs, bays, and straits. Sometimes the land is broken into islands, and sometimes islands are joined to the continent.

There are no portions of the earth's surface, whether it be land or water, that are not more or less subject to earthquakes; and records of their destructive effects have been transmitted to us through every age. The first earthquake particularly worthy of notice was that which, in A.D. 63, destroyed Herculaneum and Pompeii. In the fourth and fifth centuries, some of the most civilised parts of the world were almost desolated by these awful visitations. Thrace, Syria, and Asia Minor, according to contemporary historians, suffered most severely. On January 26, A.D. 447, subterranean thunders were heard from the Black Sea to the Red Sea, and the earth was convulsed, with little intermission, for the space of six months; and in Phrygia, many cities and large tracts of ground were swallowed up. On May 30, A.D. 205, the city of Antioch was overwhelmed by a dreadful earthquake, and 250,000 of its inhabitants are said to have been crushed in its ruins.

In the year 1346, Asia Minor and Egypt were violently shaken; and in the following year severe earthquakes were experienced in Cyprus, Greece, and Italy.

In 1692, the island of Jamaica was visited by a terrible earthquake, in which enormous masses of earth were detached from the Blue Mountains; and vast quantities of timber, hurled from their flanks, covered the adjacent sea, like floating islands. It was during this earthquake that the city of Port Royal, with a large tract of adjacent land, sank instantaneously into the sea. In the following year great earthquakes occurred in Sicily, which destroyed Catania and 140 other towns and villages, with 100,000 of their inhabitants.

Since the records of history, there have been no earthquakes equal in intensity to those which ravaged different parts of the world in the eighteenth century over the convulsion which in 1746 nearly laid waste Lower Peru, and those by which in 1760 the ancient town of Concepcion in Chili was totally destroyed, we come to 1755, when the city of Lisbon was almost wholly destroyed by one of the most destructive earthquakes which ever occurred in Europe. It continued only six minutes; but such was the violence of the convulsion that in that short space upwards of 60,000 persons are said to have perished. The pheno-

EARTHQUAKES

mena that accompanied it were no less striking. The sea first retired and laid the bar dry; it then rolled in, rising fifty feet or more above its ordinary level. The largest mountains in Portugal were shaken from their foundations; and some of them opened at their summits, which were split and rent in a wonderful manner, huge masses of them being thrown down into the subjacent valleys. But the most remarkable circumstance which occurred at Lisbon during this catastrophe was the entire subsidence of the New Quay, called Cays de Prada, to which an immense concourse of people had fled for safety from the falling ruins. From this hideous abyss, into which the quay sank, not one of the dead bodies ever floated to the surface; and on the spot there is now water to the depth of 100 fathoms. This earthquake excited great attention, from the extent at which contemporary shocks were experienced. The violence of the shocks, which were accompanied by a terrific subterranean noise like the loudest thunder, was chiefly felt in Portugal, Spain, and Northern Africa; but the effects of the earthquake were perceived in almost all the countries of continental Europe, and were even experienced in the West Indies, and on the Lake Ontario in North America. During the next twenty years, various earthquakes occurred in different parts of the world, attended with more or less destructive consequences. In 1759, Syria was agitated by violent earthquakes, the shocks of which were protracted for three months, throughout a space of 10,000 square leagues, and levelled to the ground Accon, Saphat, Balbeck, Damascus, Sidon, Tripoli, and many other places. In each of these places many thousands of the inhabitants perished; and in the valley of Balbeck alone, 20,000 persons are said to have been victims to the convulsion. In 1766, the island of Trinidad and great part of Columbia were violently agitated by earthquakes. In 1772, the lofty volcano of Papandayang, the highest mountain in Java, disappeared, and a circumjacent area, fifteen miles by six, was swallowed up. In 1783, the north-eastern part of Sicily and the southern portion of Calabria were convulsed by violent and oft-repeated shocks, which overthrew the town of Messina, and killed thousands of its inhabitants. In the same year the islands of Japan, Java in 1786, Sicily and the Caraccas in 1790, Quebec in 1791, and the Antilles and Peru in 1797, were violently agitated by convulsions of this kind.

Since the commencement of the present century, various earthquakes have occurred both in the Old and New World. In 1811, violent earthquakes shook the valley of the Mississippi, by which lakes of considerable extent disappeared, and new ones were formed. In 1812, Caraccas was destroyed, and upwards of 12,000 of its inhabitants buried in the ruins. In 1815 the town of Tombora, in the island of Sumbawa, was completely destroyed by an earthquake, which extended throughout an area 100 miles in diameter, and destroyed 12,000 persons. In 1819, a violent earthquake occurred at Cutch, in the delta of the Indus, by which,

among other disastrous consequences, the principal town, Bhoog, was converted into a heap of ruins. In 1822, Aleppo was destroyed by an earthquake. In the same year Chili was visited by a most destructive earthquake, from which the coast for 100 miles is stated to have been raised from two to four feet, while about a mile inland from Valparaiso it was raised from six to seven feet. In 1827, Popayan and Bogota suffered severely from earthquakes, during which vast fissures opened in the elevated plains around the latter city. In 1836, the town of Concepcion, in Chili, was entirely demolished by an earthquake. In 1837, the countries along the eastern extremity of the Mediterranean, especially Syria, were violently agitated by an earthquake, which caused great damage to the towns of Damascus, Acre, Tyre, and Sidon, and entirely destroyed Tiberias and Safet. Such are some of the most violent earthquakes that have occurred within the period of authentic history. The reader will find in the reports of the meetings of the British Association lists of the different earthquakes that have taken place down to the year 1850; and from these it will be observed that scarcely a month elapses without being signalled by one or many convulsions in some part of the globe. Shocks of earthquakes have at different times been felt in various parts of the British islands; but they have been insignificant compared to those which have been experienced in other countries.

But though history supplies us with so large a catalogue of well-authenticated earthquakes, it is surprising that so little was done by the ancients either in investigating their causes or noticing their effects. It is only within the last century and a half, since Hooke first promulgated his views respecting the connection between geological phenomena and earthquakes, that the permanent changes effected by these convulsions have excited attention. Before that time the narrative of the historian was almost exclusively confined to the number of human beings who perished, the number of cities laid in ruins, the value of property destroyed, or certain atmospheric appearances which dazzled or terrified the observers. The creation of a new lake, the engulfing of a city, or the raising of a new island, are sometimes, it is true, adverted to, as being too obvious or of too much geographical interest to be passed over in silence. But no researches were made expressly with the view of ascertaining the amount of depression or elevation of the ground, or any particular alterations in the relative position of sea and land; and very little distinction was made between the raising of soil by volcanic ejections, and the upheaving of it by forces acting below. The same remark applies to a very large proportion of modern accounts; and how much reason we have to regret this deficiency of information appears from this, that in every instance where a spirit of scientific enquiry has animated the eye-witnesses of these events, facts calculated to throw light on former modifications of the earth's structure are recorded. There can be little doubt as to the unity of cause in volca-

EARTHQUAKES

noes and earthquakes. [VOLCANOES.] Earthquakes frequently precede violent volcanic eruptions, and often seem to arise from explosive matters accumulating their force from want of vent.

The agitation of the sea during earthquakes has often been remarked, and probably such effects are more common than is supposed, for irregularities in its motion have been at times observed, which cannot be referred to temporary currents or winds in the offing. The movement is generally a quick flow and reflow of the water, often so trifling as to escape the attention of all ordinary observers, though detected by seamen and fishermen, who are surprised to find boats suddenly floated, or as suddenly left dry.

During the Lisbon earthquake, many of the rivers and lakes of Great Britain were singularly disturbed. Loch Lomond suddenly rose between two and three feet, and as suddenly subsided.

In the great Calabrian earthquake, in 1783, the aspect of the country was singularly changed. The earth appears to have had an undulating, vibratory, and horizontal motion; there were the usual tremors in the neighbouring ocean; numerous deep and extensive gaps and fissures were formed, and faults and dislocations in the strata; large landlips took place, and extraordinary lacerations; large buildings and farms were engulfed; and in some places the chasms closed upon their prey with such violence that on excavating afterwards to recover articles of value, the workmen found detached parts of buildings jammed together in one compact mass. Some of the resulting gaps and ravines were upwards of a mile long, and from 200 to 300 feet deep and broad. Lakes were formed, sometimes filled with thermal waters from below, and sometimes the consequence of the obstruction of streams; land and houses were in some places uplifted, in others depressed, in others transferred with all their plantations to a distance varying from a few feet to upwards of a mile.

In the history of earthquakes it is a matter of much geological importance to establish clearly the fact of elevations and depressions of districts and strata; and, if possible, to ascertain the amount of such change. Upon these points the Chilian earthquake of 1822 affords some satisfactory evidence. The shock is said to have extended for more than a thousand miles along the coast, and a great part of the country was bodily elevated for a length of more than a hundred miles; the beach and the bottom near the shore being raised from three to four feet. The uplifting of the former was rendered evident by the adhesion of the shells to the rocks; and it was observed that there were other lines of beach above that newly elevated, attaining in parallel lines a height of about fifty feet above the sea, seeming to show that previous elevations had been effected by the same causes. An old wreck of a ship, which before could not be approached, became accessible from the land; cones of earth were

thrown up in several districts by the forcing up of water, mud, and sand, through funnel-shaped hollows. The elevation inland appeared, by the effect upon water-courses, to have been two or three times greater than upon the beach.

The parts of the earth subject to earthquakes are not only very widely extended and very numerous, but the total number of these disturbances recorded is enormous. The following tabular statement will illustrate this, the greatly increased number within the present century being rather an indication that more attention has lately been given to the subject than that the proportion is now larger than before:—

	Previous to 18th Century	From 18th to 19th Century	Total
Scandinavian peninsula and Iceland	139	118	257
British Islands	124	110	234
Iberian peninsula	135	85	220
France, Belgium, and Holland	602	292	894
Basin of the Rhine and Switzerland	384	178	562
Basin of the Danube	173	145	318
Italian peninsula	384	478	862
Algeria and North Africa	—	—	63
Turco-Hellenic peninsula and Syria	373	197	570
Basin of the Atlantic	—	—	140
Canada and the United States	98	51	149
Mexico and Central America	37	30	67
The West Indian Islands	112	195	307
Chili and La Plata	24	170	194
	3,085	2,039	5,124

It is evident that very large districts of the earth are eminently subject to earthquakes. They occur also very frequently; for if the last fifty years have given such extraordinary results, compared with all previous time, it is so only because then, for the first time, the phenomena were specially recorded. It must also be remembered that earthquakes are only recorded in those limited districts of land peopled by races of men civilised and intelligent enough to be interested and not merely frightened by the convulsions of nature. We may conclude that more than sixty earthquakes take place on an average each year on the parts of the earth subject to observation, and of these about one in every eight months is on a large and important scale.

Since 1846 experiment has been brought to bear upon the enquiry, and in the hands of Mr. Mallet and others the young science of SEISMOLOGY (under which term we shall give a brief account of scientific investigation on the subject) has taken its place as a branch of cosmical physics. The earthquake of October 6 and 8, 1863, will long be remembered as one of the most severe ever felt in England, which is fortunately situated at a great distance from the regions frequently devastated by these startling phenomena. Other recent earthquakes occurred on the 9th of November, 1862,

when walls were thrown down at Shrewsbury, and on March 17, 1843, when buildings were damaged in the north of England.

Earwig. [DERMATTERA; FORFIGULA.]

Easel (Ger. *escl*, an *ass*). In Painting, a wooden frame used for supporting a picture during the progress of its execution.

Easement. In Law, a convenience which one man has of another, his neighbour, by grant or prescription. Easements were included in the Roman law under the title *servitudes*; such are a way over the lands of another, or a water-course.

East (Ger. *ost*). The point of the horizon at which the sun rises at the time of the equinoxes; or the point determined by a perpendicular to the meridian drawn towards the quarter of sunrise. The *east* is one of the four *cardinal points* of the compass.

East India Company. A famous joint-stock association originally established to carry on the trade between this country and the East Indies, or rather with the countries to the eastward of the Cape of Good Hope. It was constituted by royal charter in 1600, and continued, notwithstanding repeated efforts to open the trade, to enjoy the exclusive privileges originally conceded till 1688. At that period the power of the crown to restrain the freedom of trade without the sanction of parliament having been denied, a rival association obtained an Act of Parliament in its favour; but after a variety of negotiations, which it is unnecessary to specify, the two corporations were joined in 1702 under the name of 'The United Company of Merchants trading to the East Indies;' an appellation which has been continued to the present day. In 1708 the United Company

as secured by parliament in the ancient privilege of trading to all places eastward of the Cape of Good Hope to the straits of Magellan; and this privilege, with some modifications, was confirmed and prolonged by successive Acts of Parliament down to 1814. By the Act 53 Geo. III. c. 133, passed in 1813, the East India Company's charter was renewed for twenty years: but it then received some important modifications, by which a restricted intercourse with the whole of the company's Indian possessions was permitted to all British merchants; the monopoly of the trade between England and China being, however, retained in the hands of the East India Company. These concessions paved the way for the Act of 1833, by which, though the company's charter was prolonged till 1854, not only was the monopoly of the China trade abolished, but an end wholly put to the company's original character of a commercial association.

But it is not as a commercial association so much as a great territorial power, that the East India Company became distinguished. The first establishments of the English in India, as of other European nations, arose out of the alleged necessity of providing armed stores or strongholds, where the adventurers might warehouse their goods, and reside in

safety for the purpose of carrying on their intercourse with the natives; but the factories speedily degenerated into fortifications, and the garrison into armies. For a while the power of the English and French was pretty nearly balanced in India; but the talents and victories of the famous Lord Clive gave us a decided superiority over every competitor, foreign or native, and extended our sway over some of the largest and finest portions of the Mogul empire. The policy of Clive, whether it was really approved by the succeeding governors-general of our Indian dominions, or forced upon them by necessity, has, some few short intervals excepted, been steadily followed up; and with such signal success, that our Indian empire, including protected states, comprises at present the whole of the peninsula from the Himalaya Mountains to Cape Comorin.

Under the Act 3 & 4 Wm. IV. c. 85, for continuing the charter till 1854, the functions of the East India Company were rendered wholly political. It was to continue to govern India, with the concurrence and under the supervision of the Board of Control [CONTROL, BOARD OF], nearly on the plan laid down in Mr. Pitt's Act, in 1784, by which the Board of Control was constituted. All the real and personal property belonging to the company on April 22, 1834, was vested in the crown, and to be held or managed by the company in trust for the same; subject, of course, to all claims, debts, contracts, &c. already in existence, or that may hereafter be brought into existence by competent authority. The company's debts and liabilities were all charged on India; the dividend, to continue at 10½ per cent., to be paid in England out of the revenues of India; and provision was made for the establishment of a *security fund* for its discharge. The dividend may be redeemed by parliament, on payment of 200*l.* for 100*l.* stock, any time after April, 1874.

The company's stock forms a capital of 6,000,000*l.*, into which all persons, natives or foreigners, males or females, bodies politic or corporate (the Governor and Company of the Bank of England only excepted), are at liberty to purchase, without limitation of amount. Since 1793, the dividends have been 10½ per cent., to which they are limited by the already cited.

The proprietors in general court assembled were empowered to enact by-laws, and in respects were competent to the complete investigation, regulation, and control of every branch of the company's concerns; but, for the prompt despatch of business, the executive department was vested in a court of directors. A general court was required to be held once in the month of March, June, September, and December, in each year. No one could be present at a general court unless possessed of 500*l.* stock; nor vote upon the determination of any question unless in possession of 1,000*l.* stock for the preceding twelve months, unless such stock had been obtained by bequest or marriage. Persons

EAST INDIA COMPANY

possessed of 1,000*l.* stock were empowered to give a single vote; 3,000*l.* made a qualification for two votes; 6,000*l.* for three votes; and 10,000*l.* and upwards for four votes. Upon any special occasion, nine proprietors, duly qualified by the possession of 1,000*l.* stock, might, by a requisition in writing to the court of directors, call a general court; which the directors were required to summon within ten days, or, in default, the proprietors might call such court by notice affixed upon the Royal Exchange. In all such courts the questions were decided by a majority of voices; in case of an equality, the determination to be by the treasurer drawing a lot. Nine proprietors might by a requisition in writing demand a ballot upon any question, which could not be taken within twenty-four hours after the breaking up of the general court.

The court of directors was composed of twenty-four members, chosen from among the proprietors, each of whom must be possessed of 2,000*l.* stock; nor could any director, after being chosen, act longer than while he continued to hold stock. Of these, six were chosen on the second Wednesday in April in each year, to serve for four years, in the room of six who had completed such service. After an interval of twelve months, those who had gone out by rotation were eligible to be re-elected for the ensuing four years. The directors chose annually from amongst themselves a chairman and a deputy-chairman. They were required by by-laws to meet once in every week at least; but they frequently met oftener, as occasion required. Not less than thirteen could form a court. Their determinations were guided by a majority. In case of an equality, the question must be decided by the drawing of a lot by the treasurer: upon all questions of importance, the sense of the court was taken by

ballot. The company's officers, both at home and abroad, received their appointments immediately from the court, to whom they were responsible for the due and faithful discharge of the trust reposed in them.

The principal powers of the court of directors were vested in a secret committee, forming a sort of cabinet or privy council. All communications of a confidential or delicate nature between the Board of Control and the company were submitted, in the first instance at least, to the consideration of this committee; and the directions of the board, as to political affairs, might be transmitted direct to India, through the committee, without being seen by the other directors. The secret committee was appointed by the court of directors, and its members sworn to secrecy.

The territorial possessions of the East India Company were divided into the three presidencies of Bengal, Madras, and Bombay, at each of which the executive government was administered by a governor and three councillors, the governor of the Bengal presidency being at the same time governor-general of India. In their several presidencies, the governors and their councillors possessed the privilege of enacting and enforcing laws; subject, however, in some cases, to the concurrence of the supreme court of judicature, and, in all cases, to the approval of the court of directors and the Board of Control.

The following table (*Parliamentary Paper*, 1851), of which, however, it would be unsafe to guarantee the exactness, represented the area and population under the dominion of the company in 1851, not long before the period when it ceased to reign. Subsequently, however, it acquired the Punjab, and considerable tracts of territory in Burmah and elsewhere:—

		Population	
BRITISH STATES.		sq. miles	sq. miles
Bengal		325,652	47,958,320
North-Western Provinces		85,571	23,800,649

EAST INDIA COMPANY

Such was the height of power to which this celebrated body had attained, when the terrible outbreak of the Sepoy mutiny of 1857-8 occurred. It was repressed at a great expenditure of life and treasure, and mainly by the energy and political ability of the civil and military servants of the company itself. Nevertheless, this great event combined with many other causes to induce parliament and the public to believe that the time had arrived when the dominion of India ought to be transferred to the crown. The change was effected, after much discussion, by the Act 'for the Better Government of India,' 21 & 22 Vict. c. 106 (1858). The government of India, under the crown, was vested in a secretary of state and

council, the latter consisting of fifteen members, partly nominated by the crown and partly elected by the whole body. The council now comprises several of those directors who took the most active part in the administration of the affairs of the company. The company itself is continued in existence by certain clauses of the Act, for the purpose of managing its funds, &c.; but its powers as a governing and as a commercial body have ceased altogether.

The subjoined return contains an account of the various stocks, loans, debts, &c. of the company, and subsequently of the crown government of India, including the 6,000,000*l.* of India stock already described:—

Return of all Stocks, Loans, Debts, and Liabilities chargeable on the East India Revenues, at Home and Abroad, up to the latest Period of Time to which such Return can be made out: viz. England, December 31, 1864; India, April 30, 1863.

Easter (Ger. *oster*). The festival which is held in commemoration of our Lord's resurrection. The term, according to Bede, is derived from *Eostra*, which seems to be the same name as *Ashtaroth*.

The Jews celebrated their passover on the fourteenth day of the month *Nisan*, being the lunar month of which the fourteenth day either falls on, or next follows, the day of the vernal equinox. In the year of our Lord's crucifixion this fell on a Friday: the resurrection, therefore, took place on the first day of the next week, thence denominated the *Lord's day*. The primitive Christians in their desire to celebrate this anniversary rightly fell into two different systems. The Western churches observed the nearest Sunday to the full moon of *Nisan*, taking no account of the day on which the passover would be celebrated. The Orientals, on the other hand, following the Jewish calendar, adopted the fourteenth of *Nisan* upon which to commemorate the

on the third day following, upon whatever day of the week that might fall; hence they obtained the name of *Quartodecimantes*: the former appealed to the authority of St. Peter and St. Paul, the latter to that of St. John.

The dispute upon this point in the second and third centuries is remarkable, as connected with perhaps the first event which can be brought to bear on the question of the primacy of the bishop of Rome; and it is the more interesting as both parties claim it as a testimony in favour of their own views. Victor, bishop of Rome, wrote an imperious letter to the Oriental bishops, requiring their conformity to the Western rule; which was answered by Polycrates, bishop of Ephesus, in the name of the rest, expressing their resolution to maintain the custom handed down to them by their ancestors. The Romish bishop thereupon broke off communion with them; but he was rebuked by Irenæus of Lyons, and it was agreed by his mediation that each party should retain its

own customs. Such continued to be the practice till the time of Constantine, when the council of Nice determined the matter by the following canons:—

1. Easter must be celebrated on a Sunday.

2. This Sunday must follow the fourteenth day of the paschal moon; so that if the fourteenth day of the paschal moon falls on a Sunday, then Easter must be celebrated on the Sunday following.

3. The paschal moon is that moon of which the fourteenth day either falls on, or next follows, the day of the vernal equinox.

4. The 21st day of March is to be accounted the day of the vernal equinox.

The new moons, it is necessary to observe, are those of the ecclesiastical calendar, which are determined arbitrarily (by the lunar cycle in the Julian calendar, and by means of the table of epochs in the Gregorian); so that the above rules define Easter without ambiguity. The new moons of the calendar are in general one or two days, sometimes even three days, later than the astronomical or true new moons; and the fourteenth day of the moon is accounted the full moon, although the opposition takes place more frequently on the sixteenth day. [CALENDAR; EPOCH.]

Easy. The Sea phrase for a ship that moves over the sea without jerking or straining. In steamboats it is also the word of command to the engineer when a less degree of speed is required: in this sense it is also pronounced *ease her*.

Eau de Cologne (Fr.). A perfumed spirit originally prepared at Cologne, and principally used as a perfume; though many imaginary medical virtues have also been ascribed to it. Various recipes have been published for the preparation of eau de Cologne. The following affords a good imitation of the original article: Take of alcohol one pint; of the oils of bergamot, orange-peel, and rosemary, each one drachm; of bruised cardamom seeds, one drachm; orange-flower water, one pint; distil one pint from a water-bath.

Eau de Javelle. A bleaching and disinfecting solution of chloride or hypochlorite of soda.

Eau de Luce. A strong solution of ammonia, scented and rendered milky by the addition of a little mastic and oil of amber. It is considered an effective remedy in India against the bite of poisonous snakes.

Eau Médicinale (Fr.). Under this name a remedy for the gout was first brought into notice by Huxson, a French officer. It attained great celebrity in this country about fifty years ago, and was much used till it was discovered that it was a vinous tincture of colchicum, since which it has fallen into disuse, and the official preparations of that drug have become its substitutes.

Eaves (A.-Sax. *efese*, a margin or edge). In Architecture, the lowest edges of the inclined sides of a roof which project beyond the face of the wall, so as to throw off the water therefrom.

The eaves sometimes are provided with a semi-circular cast-iron gutter and a down pipe, at other times they discharge the water upon the bare ground without the intervention of any gutter.

Ebbing of the Tide. The reflux of the tide. [TIDE.]

Ebenaceæ (Ebenus, one of the genera). A natural order of shrubby or arborescent Exogens of the Gentianal alliance, chiefly inhabiting the tropics. They are allied to *Oleaceæ*, with which they agree in the placentation of their seeds; but are distinguished by their alternate leaves and axillary flowers, which are usually unisexual. They are more closely related to *Aquifoliaceæ*, but differ in the number of their stamens and in their divided sexes. Some species are remarkable for the hardness and blackness of their wood, known under the name of Ebony and Iron-wood; others, as the *Kaki* of China, yield an eatable fruit. All are beautiful objects when growing.

Ebionites. An ancient sect (referred by Mosheim to the second century), who believed in Christ as an inspired messenger of God, but considered Him to be at the same time a mere man, born of Joseph and Mary. They maintained also the universal obligation of the Mosaic law, and rejected the authority of St. Paul. The origin of their name is uncertain, some deriving it from that of their supposed founder: others deduce it from a Hebrew word signifying poor, and suppose the title to be given to them in reference either to the poverty of the class to which they mostly belonged, or the meanness of their doctrine.

Eblanin. A yellow crystalline substance, resulting from the action of potash on wood-spirit. [PYROXANTHINE.]

Ebenite. A hard black compound obtained by blending caoutchouc or gutta percha with variable proportions of sulphur.

Ebony. The heart-wood of various species of *Diaptyros*. Mauritius Ebony comes from *D. Ebenum*; Coromandel Ebony is the wood of *D. Melanoxylon*; and the Bastard Ebony of Ceylon, that of *D. Ebenaster*. Ebony is heavier than water, takes a good polish, and gives off an aromatic odour when burnt.

Ebulliscope. An instrument for ascertaining the strength of spirit of wine, by the careful determination of its boiling point.

Ebullition (Lat. *ebullio*, I bubble up). The motion produced in a liquid by its rapid conversion into vapour.

Écarté (Fr. *discarded*). A game at cards for two persons, very popular in France. It is played with a piquet pack of 32 cards, all from the 6 to the 2 being excluded. The king ranks as the highest card; the ace ranks between the knave and 10; the other cards have the same relative value as at whist. Five cards are dealt to each player, and a trump card turned up. The non-dealer may then propose to throw out or discard any number of cards, which may be allowed or refused by the dealer, who in the former case gives an equal

ECBOLIOS

number from the pack, and may change any number himself in like manner. If the elder hand is still dissatisfied with his cards, he may propose again and again till the pack is exhausted.

When the hands are settled, the two parties play alternately, the object being to win tricks, as at whist, and the play being regulated in the same manner, except that the second player must win the trick if he can, either by a higher card, or by trumping if he cannot follow suit. The game consists of five points, which are made as follows: The party who wins three tricks out of the five makes what is called the *point*, which scores one; winning all five tricks is called the *vole*, and counts two. A king turned up scores one for the dealer; and the king of trumps held in either hand scores one for the holder, but in this case it must be declared before playing. If the non-dealer decline to take cards, and lose the point, his opponent scores two for it instead of one; and if the dealer refuse to give cards on the first asking, and the opponent make the point, it scores two in like manner.

Ecboles (Gr. *ἐκβολή*, a medicine which expels the fetus). Remedies which by exciting uterine contractions promote the expulsion of the contents of the uterus. Savin and drastic purges have been termed *ecbolics*, but the only unequivocal agent of this class is *Ergot*.

Eccentric (Gr. *ἐκ*, and *κέντρον*, a centre). An arrangement of machinery by which a circular motion is converted into a horizontal or vertical one, or vice versa. It usually consists of a circular disc placed upon the prime mover, which works in a frame, in connection with the piece to which motion has to be communicated, by means of a pulley, or collar moving freely upon the secondary motor. This kind of arrangement is generally adopted for communicating movement to the valves of steam engines, in which case the weight of the pulley is balanced on the shaft by a counter weight cast upon it.

Ecclymnesia (Gr. *ἐκκλυσμός*). The extravasation of blood into the cellular membrane which results from blows and bruises.

Ecclesia (Gr. *ἐκκλησία*). In Ancient History, the great assembly of the Athenian people, at which every free citizen might attend and vote. This assembly, though nominally possessed of the supreme authority of the state from the earliest times, yet having no fixed times of meeting, was but seldom convened; so that the archons, who were elected from the body of nobles or eupatrides, had virtually the whole management of the state. But the regulations of Solon, which appointed it to meet regularly four times in every period of thirty-five days, besides extraordinary occasions on which it might be convened, called it into active energy. Solon, however, restricted the subjects discussed in the Ecclesia to such as had before passed through the senate of five hundred; but when the democratic spirit of after-times prevailed, this rule was not strictly observed. The magistrates who had

ECCELESIASTICAL

the management of these assemblies were the Prytanes [*Πρυτάνες*], the Prohedri [*Προηδρί*], and Epistates [*Επιστάταις*]. The first of these sometimes convened the people, and hung up in a conspicuous place a programme giving an account of the matters to be discussed. The *Prohedri* proposed to the people the subjects on which they were to decide, and counted the votes. The *Epistates*, who presided over the whole, gave the liberty of voting, which might not be done before his signal was given.

The forms of their proceedings were as follows: First, an expiatory victim was sacrificed, and his blood carried and sprinkled round the bounds of the assembly. Then the public crier demanded silence, and invited all persons above fifty years of age to speak; after that, anyone who pleased. After the subject was discussed, they proceeded to vote on the crier's demanding of them, 'whether they would consent to the decree proposed to them?' The votes were commonly given by show of hands, but on some occasions by ballot. When the suffrages had been examined and their numbers declared, the *Prytanes* dissolved the assembly. In order to incite the people to attend the Ecclesia, a small pay of one or three oboli was given for early appearance; and a rope, rubbed with vermillion, was carried through the Agora, to mark such as lagged behind, who were accordingly fined. From this, the most famous of Grecian public assemblies, the name passed to designate public assemblies regularly convoked in general: as in the Book of Acts the 'meeting' of the citizens of Ephesus is termed *ecclesia*, and those who search for the meaning of words in history can have no doubt that the word which we render *church* has in the same book the primary meaning of the regular 'meeting' or 'assembly' of Christians in any place.

Ecclesiastes (Gr.). A canonical book of the Old Testament; the word signifies 'the preacher,' and the book is popularly ascribed to Solomon.

Ecclesiastical. Something pertaining to or set apart for the church; in contradistinction to *civil* or *secular*, which regards the world. Ecclesiastics are persons whose functions consist in performing the service or in maintaining the discipline of the church. [CLERGY.]

Ecclesiastical Commissioners for England. Appointed originally in 1835 to consider the state of the dioceses of the church of England, and of the cathedral and collegiate churches, with reference to amount of revenues, &c. In pursuance of their Reports, the episcopal revenues were distributed on a new and permanent footing, approaching to equalisation: part of the revenues of collegiate and cathedral churches, with the whole endowment of non-residentary prebends and offices, was carried to a fund in order to make better provision for the cure of souls. But large sums out of the fund thus created were in fact appropriated to the construction and repair of episcopal resi-

dences. The commission was considerably enlarged in 1840 under the Act 3 & 4 Vict. c. 113.

Ecclesiastical Courts. The ordinary Ecclesiastical Courts in England and Wales are, beginning with the lowest:—

1. The Peculiar Courts, which are very numerous; Royal, Archbishop, Episcopal, Decanal, Sub-decanal, Prebendal, Rectorial and Vicarial; with jurisdiction frequently extending only to a single parish, and sometimes limited only to a part of the matters usually subject to ecclesiastical cognisance.

2. The Archdeacon's Court, generally subordinate, with an appeal to that of the bishop.

3. The Courts of Commissaries, especially appointed by the bishop.

4. The Diocesan Court of every bishop within his respective diocese.

5. The Provincial or Archbishopal Courts.

A suit is commenced in the Ecclesiastical Courts by a process, sued out by the party complaining, and served on the other party by an officer of the court. The party cited may appear either in person or by his proctor, who discharges duties similar to those of the attorneys in common law courts. A party disobeying citation may be pronounced contumacious, and imprisoned by an attachment out of the lord chancellor's court.

In case the party cited appear to show cause against his citation that the court has no jurisdiction, or that he is not amenable to it, this preliminary objection is heard upon petition and affidavits. If the judge decide against the defendant on the question of jurisdiction, the latter may apply to the courts of common law for a prohibition.

The law of the Ecclesiastical Courts is administered by men associated, as a distinct profession, for the practice of the civil and canon laws. They are incorporated as 'the college of doctors of law.' [DOCTORS' COMMONS.]

The jurisdiction of these courts may be considered as twofold: 1. In causes of a purely spiritual nature pertaining to the discipline of the church; 2. In causes of a civil nature, including some of a mixed character, partaking of the spiritual, such as suits for tithes in former times, suits respecting a right to seats in church, and the like.

1. The first of these branches arises out of the temporal power exercised by every church to correct its communicants by censures and discipline submitted to. Under this class falls the cognisance of offences committed by the clergy themselves by neglect of duty, immoral or heretical delinquencies, suffering dilapidations, &c.; also by laymen, in brawling and other indecent conduct in churches and churchyards, in neglecting to repair churches, in cases of incest, incontinence, defamation. All these, except the last, are termed *causes of correction*. The punishments inflicted are monition, penance, excommunication, suspension *ab ingressu ecclesie*, and (in the case of clergymen) suspension from office and deprivation.

In the case of laymen a great part of this jurisdiction has fallen into disuse; and the real penalty, whenever a cause is tried, consists, for the most part, in the payment of costs by the guilty party. The terrors so long attached to the process of excommunication (the only one by which ecclesiastical courts can enforce a sentence) are now matter of history. By the common law a person excommunicated was incapacitated from any legal act, and was, moreover, on certificate from the bishop, liable to imprisonment until reconciled to the church; but now, by the statute 53 Geo. III. c. 127, the writ de contumace capiendi is substituted for the old writ de excommunicato capiendi in cases of contempt; and in the few cases in which excommunication is still pronounced as a sentence, the court is empowered to assign a term of imprisonment not exceeding six months. 2. In causes of a civil nature the functions of these courts may now be said to have very nearly ceased. These were divided into causes pecuniary, of which the greater part were extinguished by the abolition of tithes: matrimonial; abolished by 20 & 21 Vict. c. 85 [MARRIAGE] except in the matter of granting marriage licenses: testamentary; transferred in the same session, by the Act 20 & 21 Vict. c. 77, to a civil court, proceeding according to the course of the common law.

Ecclesiasticon. One of the apocryphal books of the Bible, composed, it is asserted, by Jesus the son of Sirach, and admitted by the Romish church into the canon of the Old Testament. This book was originally written in Syro-Chaldaic, and consists chiefly of meditations on religion and the conduct of human life.

Ecclesiology. A modern term denoting the science of church architecture, fittings, arrangements, and symbolism.

Eccoprotics (Gr. *ek*, out, and *ekpros*, excrement). The term formerly applied to mild aperient medicines.

Ecdysis (Gr. *ekdysis*, a stripping). The moulting of the skin.

Echelon (Fr.). Signifies the position of a body of troops, when its divisions are so formed as to be behind one another in the form of steps. Formations in echelon are of two kinds—direct and oblique.

Echidna (Gr. *ἐχίδνα*, an adder). In Mythology, a monster, half-maid and half-serpent, of whom there are many legends, all varying greatly in detail. One myth, which connects her with Hercules and the Scythians, is given by Herodotus (iv. 8–10). For the meaning of the word, see Max Müller's *Lectures on the Science of Language*, first series, p. 366.

ECHIDNA. In Zoology, a name proposed by Cuvier for a genus of Australian quadrupeds, having the general form of an ant-eater, but covered with spines. The *Echidna*, like the *Ornithorhynchus*, deviates in a remarkable manner from the typical structure of the mammalia in general in the organisation of the generative and osseous systems, and forms with it a family or order called *Monostruma*

ECHIDNINE

[see that word]. In the male of the *Echidna*, as in the *Ornithorhynchus*, the hind foot is armed with a curved spur, perforated like the fang of a viper by the duct of a poison gland, whence probably the reason for the name. Among the colonists of Australia, the *Echidna* is generally known by the name of the porcupine. It frequents sandy localities, lives in burrows, and feeds on ants and other insects, which it entraps by means of a long and adhesive tongue.

Echidmine. *Serpent Poison.* The secretion from the poison-glands of the viper and other serpents. It is a clear, viscid, neutral, yellowish fluid, containing albumen, mucus, fatty matter, and a yellow colouring principle; and among its salts, phosphates and chlorides. Associated with the albumen is a peculiar nitrogenous body to which the term *echidnine* has been more specially applied. The poison-bag of the viper seldom contains more than two grains of the poisonous liquid: 1-250th of a grain is sufficient to kill a small bird.

Echinate (Gr. *ἐχίνος*, a hedgehog). In Botany, furnished with rigid hairs or prickles, as the husk of the Sweet Chestnut.

Echinococcus (Gr. *ἐχίνος*, and *κόκκος*, a cyst). A genus of Hydatids or Cystic Entozoons, of which one species (*Echin. hominis*) is recorded by Rudolphi as infesting occasionally the human subject.

Echinodermata, Echinoderms, Echinoderma (Gr. *ἐχίνος*, and *δέρμα*, skin). A name applied to a class of Invertebrate Radiate animals, which have a crustaceous or coriaceous integument, most commonly armed with tubercles or spines. They are classified as follows:

Order: *Crinoidea*.

Families: Encrinuræ.
Comatulidæ.

Order: *Asteroidea* (Starfishes).

Families: Ophiuridæ.
Stelleridæ.

Order: *Cystoidea*.

Order: *Echinoidea* (Urchins).

Families: Clypeasteridæ.
Echinidæ.
Spatangidæ.

Order: *Holothurioidæ* (Sea-cucumbers).

Families: Holothuridæ.
Synaptidæ.

Order: *Sipunculoidæ*.

Families: Sipunculidæ.
Echiuridæ.

Echinopora (Gr. *ἐχίνος*, and *πόρος*, a pore). A subgenus of *MADREPORÆ* [see that word].

Echinus (Gr. *ἐχίνος*). The generic name of the Sea-urchins, which constitutes the type of the class *Echinodermata*. The Linnæan genus is now subdivided into many subgenera; some of which have their names compounded of *Echinus* and some other word, as *Echinobrisus*, *Echinodiaris*, *Echinoclypeus*, *Echinoconus*, *Echinocorys*, *Echinocyamus*, *Echinodiscus*, *Echinonampus*, *Echinometra*, *Echinoneus*, *Echinorodon*, &c.

ECHO

ECHINUS. In Architecture, the name of the cushion or capital of the Doric order, from the circumstance that originally this member was painted with the echinus, the ornament commonly known as the *egg and tongue*. The painted ornaments have perished; but the Doric pillars of later times, executed after the custom was established of cutting or carving the ornamental details, have this decoration perfectly preserved. It is also one of the most characteristic running ornaments of the earlier period of Greek art, and abounds in the decorations of the Erechtheum.

Echo (Gr. *ἠχώ*, sound). A sound reflected from a distant surface, and repeated to the ear. Though echo is a simple consequence of the reflection of sound, several conditions must be fulfilled before it can be produced. In the first place it is necessary that the ear be situated in the line of the reflection; and in order that the person who emits the sound may himself hear the echo, this line must be perpendicular to the reflecting surface, at least if there is only one reflecting surface; but if there are several such surfaces properly disposed, the sound may be brought back by a series of successive reflections to the point from which it emanated. In the second place, it is necessary that the opposing surface be at a certain distance from the ear; for if the direct and reflected sounds succeed each other with great rapidity, they are in some measure confounded, and the echo cannot be distinguished. Hence large rooms and vaulted caves have a strong *resonance*, but no echo is produced by them, the proximity of the walls rendering it impossible to distinguish the reflected sounds.

Observation proves that sound passes through the atmosphere at the rate of about 1,125 feet in a second; hence a person placed at half that distance, or 512 feet from the reflecting surface, would hear the echo exactly one second after the sound was emitted by him, and the echo would repeat as many distinct sounds as the ear can distinguish in a second. The utmost number of sounds which any ear can distinguish in a second perhaps does not exceed ten; hence the least distance of the reflecting surface from the point whence the sound is emitted must be about fifty feet, in order that an echo may be produced.

Everything which is capable of reflecting sonorous pulses may cause an echo; whence the wall of a house, or the rampart of a city, a wood, rocks, or mountains, produce echoes. Unless, however, the surface which reflects the sound is of considerable extent, the echo will be too feeble to be heard. A certain degree of concavity in the surface, by which several diverging rays of sound are collected and concentrated at the point where the echo is audible, is at least highly favourable, if not absolutely essential, to the production of echoes. It is a property of the ellipse that every sound proceeding from one of its foci, and imaging against the curve, is reflected into

the other focus; whence two persons placed in the two foci of an elliptic chamber may converse with each other in a whisper, and their voices not be heard by those who are in the other parts of the room. Hence also walls or buildings approaching to the elliptic form return sounds with great distinction and force. In the whispering gallery of St. Paul's, the faintest sound is conveyed from one side of the dome to the other, but is not heard at any intermediate point. In Gloucester cathedral a gallery of an octagonal form conveys a whisper seventy-five feet across the choir at its eastern end. Some echoes are remarkable for their frequency of repetition. An echo in Woodstock Park repeats seventeen syllables by day and twenty by night. Southwell (*Phil. Trans.* 1786) describes an echo in the Simonetta palace, near Milan, which repeated the report of a pistol sixty times. In Birch's *History of the Royal Society*, an account is given of an echo at Ronesath, near Glasgow, that repeats a tune played with a trumpet three times, completely and distinctly.

ECHO. In Architecture, a term often applied, though incorrectly, to vaults, or arches, usually of an elliptical or parabolical form, made for the purpose of producing artificial echoes.

ECHO. In Mythology. [NARCISSUS.]

Mechometer. In Music, a sort of scale or rule, marked with lines which serve to measure the duration of sounds, and to ascertain their intervals and ratios.

Eclectics (Gr. *ἐκλεκτικοί*). Those philosophers who endeavour to select from the systems of various schools those doctrines alone which are true, and to present these in the form of an entire whole. An eclectic spirit, it is evident, can only arrive at a period of some maturity in philosophical speculation. Whether or not it is to be regarded as an evidence of the decay of original power in the age in which it appears, must depend on the less or greater coherence in the system when completed. In one sense of the word, Plato and Aristotle may be regarded as eclectics. They both availed themselves largely of the labours of their predecessors. Plato, in particular, comprehended in his scheme of philosophy the whole of more than one foregoing system; as the doctrine of Heraclitus of the perpetual flux of sensible objects and the consequent uncertainty of sensible impressions. But in the hands of these great thinkers the *discerpta membra* are reunited, and endued with a principle of vitality as constituent parts of a harmonious whole. The same cannot be said of others who have adopted a similar method; especially of most of those to whom the term *eclectic* has been more peculiarly applied. These philosophers lived chiefly under the Roman empire. The most celebrated among them may be said to have been Epictetus (A.D. 90) and Plutarch. The latter, in particular, a man of great and various endowments, may yet be taken as a striking instance of a false eclecticism. His great object, in his philosophical writings, seems to have been to re-

concile the profound speculations and pure morality of the philosophers with the fanciful inventions and the gross theology of the poets and priests of Greece, Italy, or Egypt.

A far more favourable specimen of the eclectic spirit has been afforded us in modern times in the person of M. Victor Cousin, perhaps the most able and ingenious thinker of modern France. See his *Lectures on the History of Philosophy*.

Eclipses (Gr. *ἐκλείψις*, from *ἐκλείπω*, *I faint away or disappear*). Taken in a general sense, eclipses are phenomena produced by the obscuration of celestial bodies. They may be divided into two kinds, according to the circumstances under which they occur; viz. 1. When the obscuration is caused by an interception of the light received by the body from the sun; as in the cases of eclipses of the moon, eclipses of Jupiter's satellites, &c. 2. When the obscuration is caused by an interception, either totally or partially, of the light transmitted from the luminary to the spectator; this latter class embraces eclipses of the sun, occultations of stars and planets by the moon, the transits of Mercury and Venus over the disc of the sun, and of the satellites of Jupiter and Saturn over the discs of those planets. The eclipses of Jupiter's satellites, which can be calculated long beforehand, afford an extremely convenient method of determining longitude.

The most popular and generally interesting objects are the eclipses of the sun and moon. The earth and moon cast their shadows in directions opposite to the sun. As the figures of the bodies are nearly spherical, and as the sun is larger than either, it is plain that these shadows must be very nearly of a conical form. The moon is eclipsed when it becomes involved in the shadow of the earth, and so deprived of the light which it otherwise would receive from the sun. This can take place only at the time of full moon, or when the moon is in opposition to the sun. Let S represent the sun, E the earth, and $n'n'$ its conical shadow, into which the rays of the sun do not enter. This shadow must evidently be a portion of the larger cone T't' which envelopes both bodies. Suppose the plane of the paper to be the plane of the ecliptic, or the plane in which the earth moves round the sun, and let $\epsilon\epsilon'$ represent a portion of the path of the moon round the earth, the arrows

Fig. 2.

indicating the direction of her motion. Conceive also by means of cross tangents T P ϵ , T' P ϵ' the two opposite and circumscribing cones T P T', ϵ' P ϵ to be drawn. The latter of these cones, ϵ' P ϵ , is called the *pennumbra cone*; and the space N n N', projected beyond the earth, the *earth's penumbra*. It is evident that any

ECLIPSES

position within this penumbra is at least partially deprived of the light of the sun; for if we imagine a spectator to be in that position, it is obvious that the interposition of the earth would act as a partial screen and obscure a portion of the sun's disc from his view. It is also evident that a greater portion of the disc of the sun would be hidden from this supposed spectator as his position approaches nearer to the earth's shadow or *umbra*; and that if we suppose him to enter the shadow, he will become totally deprived of the light of the sun, the disc in this case being entirely hidden by the intervention of the earth. From this observation it follows that as the moon advances in the penumbra from c to m her disc will receive less and less light from the sun, and its brightness will gradually diminish; also, as soon as a portion of the moon's disc enters the shadow, that portion becomes totally deprived of the light of the sun, and is, in other words, darkened or eclipsed. If in the course of the eclipse only a part of the moon's disc enters the earth's shadow, it is called a *partial eclipse*; but if the moon is totally darkened by the whole disc entering the shadow, it is called a *total eclipse*. It is to be understood in the diagram that the orbit of the moon, or the path which she describes round the earth, is not in the plane of the ecliptic or the plane of the paper, but inclined to it at an angle always greater than $4^{\circ} 57'$ and less than $5^{\circ} 21'$. This is the reason why eclipses of the moon do not happen at every full moon, for they can only take place when the moon's elevation above the ecliptic at full moon happens to be less than the semidiameter of the section of the earth's shadow through which she passes. In the course of a year there may be three eclipses of the moon, which is the greatest number that can happen; but there must always necessarily be two.

At the time of new moon, or when the moon is between the sun and the earth, her shadow or penumbra may fall on the disc of the earth at certain places, and prevent either all or part of the light of the sun from reaching those places on the earth's surface. This circumstance produces the phenomenon of a total or partial eclipse of the sun, which is limited to the portion of the earth on which the moon's shadow or penumbra happens to fall. The shadow of the moon does not always reach so far as the earth. In the two following diagrams, annexed by way of illustration, the former

portion of the earth's surface between m and m' ; and the inhabitants, if any, of that portion, will evidently, from what has been said before, have the sun's disc wholly covered by the intervention of the dark body of the moon, and

Fig. 3.

therefore have presented to them a *total eclipse of the sun*. But in the second diagram, where the shadow of the moon does not reach the earth, if we suppose the dark conical shadow $n'tn'$ to be produced into the small opposite cone $m'tm'$ meeting the surface of the earth, it will be obvious, after a slight consideration, that any supposed spectator within this latter cone, or any inhabitant of the portion mm' of the earth, will perceive the dark body of the moon wholly within the disc of the sun, and intercepting only an interior part of his light; the unobscured part of the sun which circumscribes the disc of the moon will consequently present the appearance of a beautiful luminous ring or annulus, and the eclipse exhibiting this aspect is commonly called an *annular eclipse of the sun*; the cone $m'tm'$ may be similarly called the *annular cone*. It does not always occur, during the progress of an eclipse of the sun, that either the dark shadow of the moon or the annular cone will fall on the earth's surface, and it very rarely happens that either of them will fall on any defined spot, such as London or Edinburgh. For the occurrence of an eclipse on the earth, it is only necessary that the moon's penumbra $Nn'N'$ shall be projected against a portion of the terrestrial surface, as an inhabitant of that portion will at least have a part of the disc of the sun intercepted by the moon. When neither the moon's shadow nor the annular cone meets the earth in the course of an eclipse, and consequently only a part of the sun's disc is obscured to terrestrial vision, it is called a *partial eclipse of the sun*, and in that respect it is similar to a partial eclipse of the moon. If in the two diagrams we suppose, as before, the plane of the paper to be the plane of the ecliptic, the position of the moon must not necessarily be considered to be in that plane. The north pole of the earth will be directed upwards at an angle of about $23^{\circ} 28'$, and the arrows will represent the direction in which the earth revolves about its axis; the moon proceeds round the earth in the same direction, and carries her penumbra across the earth's surface with a much greater velocity than the earth's rotation. It follows, therefore, that the arrows indicate also the direction in which the phenomena of the eclipse pass geographically over the earth, viz. from west to east; and that different places will have the eclipse at a later or earlier time, according as they are more to

Fig. 2.

represents the case in which it does reach, and the latter represents the case in which it does not reach, the surface of the earth. The shadow of the moon in the first diagram falls upon a

ECLIPTIC

the east or west. Eclipses of the sun occur more frequently than eclipses of the moon. In the course of each year there must be two at least in some parts of the earth; but there cannot possibly be more than four. See also SUN for some phenomena attending solar eclipses.

Ecliptic (Gr. *ἐκλειπτικός*). In Astronomy, the great circle of the heavens which the sun appears to describe in his annual revolution. It has been called the *ecliptic* because eclipses happen only when the moon is in the same plane, or very near it. The ecliptic, from time immemorial, has been conceived to be divided into twelve equal parts, called *signs*—Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces. But the signs of the ecliptic, or as they are sometimes called the *signs of the zodiac*, must not be confounded with the constellations, which have the same name and never alter their position in the heavens. The *signs* of the ecliptic denote merely arcs of 30°; and as they are reckoned from the intersection of the equator and ecliptic, which is not a fixed point, they are carried backwards by the precession of the equinox through the constellation. Thus the *sign* Aries is now in the constellation Pisces.

The ecliptic is the circle to which longitudes and latitudes in the heavens are referred, as right ascensions and declinations are referred to the earth's equator.

The angle which the plane of the ecliptic makes with the plane of the equator is called the *obliquity of the ecliptic*. [EARTH.] The obliquity of the ecliptic on June 1, 1865, was 23° 27' 15.87". It is liable to variation from the earth's NUTATION [which see] and other causes.

Ecliptic Digits. [DIARRA.]

Ecliptic Limits. The greatest distances at which the moon can be from her nodes, in order that an eclipse of the sun or moon may happen. When the moon is within those limits at the time of the new or full moon, an eclipse certainly happens; but when the moon is beyond those limits, an eclipse cannot happen. The limits for an eclipse of the sun are about 17°, and for an eclipse of the moon about 12°.

Eclogue (Gr. *ἐκλογή*, a selection). In the original meaning of the word, the select or choice pieces of an author; or extracts collected out of former works, such as were termed in Latin *excerpta*. It is not known how this title was originally given to the pastoral poems of Virgil; but from the circumstance of their being so named, the word *eclogue* in modern usage is applied to that species of poetry. The persons who are introduced conversing in eclogues, or whose adventures are recounted in them, are shepherds; that is, for the most part, imaginary personages, whose sentiments, and the external circumstances among which they live, belong rather to an ideal age of gold than to the realities of modern life; and their loves constitute the main and proper subjects

ECONOMIC GEOLOGY

of the eclogue. Nevertheless, various writers (Gay, &c. among ourselves) have endeavoured, but with little success, to give an air of greater reality to pastoral poetry, and give their rustics more of the costume and diction of actual clowns; but the result has been a species of burlesque, not at all answering to our conceptions of pastoral poetry; nor can we easily imagine that the personages of Theocritus, although the earliest and therefore the simplest of pastoral poets, are correct resemblances of the Sicilian rustics among whom the writer lived. Some only of the eclogues of Virgil have the true character of pastorals; others are occasional poems on public and private events of the day, very slightly enveloped in the pastoral costume. The characteristics of this species of poetry, as assumed by the moderns, are: first, the representations of pastoral landscape; secondly, a slightly dramatic turn either of action or narration; thirdly, characters whose sentiments and language are confined within certain peculiar limits: thus, any strong emotion, virtue, or vice, would be an unfit topic for a pastoral poet to dwell upon. Among ourselves, Spenser, Philips, and a few others, may be named as pastoral poets in the strict sense of the word; others, as Milton in his *Lycidas*, have assumed the pastoral costume in order to convey a very different class of ideas. It is worthy of remark, that this species of composition is among those which have wholly disappeared in the present day: we have had no pastoral poet since Gay and Collins; and Gesner, in Germany, is the latest author who has acquired any degree of celebrity in this line, unless the poems of Voss, and Goethe's beautiful *Herman and Dorothea*, be placed, as they sometimes are, in this class of poems. [IDYLL; BUCOLIC.]

Economic Geology. The application of to practical and economic purposes. Much of the science is sometimes called *Practical Geology*, and it has arisen to great importance since the knowledge of geology has become definite, and the speculative has been removed from the descriptive branch of the science.

The applications of geology are many and varied. Each of them will be found treated of under special headings. To the agriculturist, the engineer, the architect, and, above all, to the miner, an acquaintance with certain departments of geology is now indispensable.

The facts of geology that chiefly bear on practical applications are these: 1. The nature and ordinary properties of the principal rocks; their various states, mechanical and chemical, and the modification they usually undergo, or are capable of undergoing in nature. 2. The sequence of rocks, and the means that exist for identifying them. 3. The mechanical disturbance and displacement of rocks. 4. The formation and filling up of those crevices, fissures, and other open spaces that affect rocks, especially those that have undergone much change whether mechanical or chemical. These

facts the original composition, the subsequent lection, and the present condition of rocks, are the basis of knowledge in economic geology. They will be found discussed at greater length in various articles. [DESCRIPTIVE GEOLOGY.]

The following are the principal subdivisions of economic geology: 1. AGRICULTURAL GEOLOGY; 2. ENGINEERING GEOLOGY; 3. ARCHITECTURAL GEOLOGY; 4. MINING. Under the heads BUILDING MATERIAL and CLAY will be found a notice of the economic geology of the varieties of clay and other plastic substances used for construction, whether on a small or large scale. QUARRYING and STRAM WORKS will also be separately noticed in reference to building stone, road metal, and certain deposits of metalliferous gravel that properly belong to Economic Geology. See also STONE.

Economy, Political. [POLITICAL ECONOMY.]

Ecostate (Lat. *e*, and *costa*, *a rib*). In Botany, applied to leaves which have no central rib or costa.

Ectheasis (Gr. *ἐκθεσις*). In Ecclesiastical History, the name given to a decree of the emperor Heraclius, issued A.D. 639, for the purpose of putting an end to the Monothelite controversy. It was probably drawn up by the patriarch Sergius, and declared the doctrine of Two Wills in Christ to be heretical. It was withdrawn by the emperor Constans, who in 648 issued his *Type*, a decree which sought to settle the question by imposing silence on both sides, and prohibiting the use of the terms, whether of the single or double will. The *Type* was condemned by Martin I. at Rome in the following year.

Ecthyma (Gr. *ἐκθύμα*, *a pustule*). A pustular skin eruption, occurring generally as the result of debility and long-continued ill-health. It may appear on the head, face, body, or extremities. When the pustules break, dark scabs remain; and these, when they fall off, leave red marks on the skin, which fade away very slowly. Ecthyma frequently occurs in old syphilitic cases. The treatment consists in the administration of tonics, especially the mineral acids and bark.

Ectropium (Gr. *ἐκτροπίω*, from *ἐκτρέπω*, *I turn away*). An unnatural eversion of the eyelids, arising from tumefaction of the inner membrane, or from a contraction of the skin covering the eyelid.

Eczema (Gr. *ἐκζεμα*, from *ἐκτίω*, *I boil or break out*). A disease of the skin, known by an eruption of small vesicles, generally very close together; but little redness is at first produced, although irritation often ensues. The heat of a summer sun sometimes produces the eruption, which has then been called *eczema solare*. Under irritation, eczema may become partly pustular, while the irritating fluid discharged from the vesicles reddens and inflames the skin, producing great distress. Bakers, grocers, and other persons whose hands come in contact with irritant

matters, sometimes suffer severely. One painful form of the disease is *eczema rubrum* or *mercuriale*, frequently seen in those who have used mercury freely, though it may also occur without any such especial cause. It affects every part of the body, and sometimes the entire skin becomes diseased. The treatment of eczema consists in improving the secretions, and supporting the system by good diet and tonics. The irritation of the skin is often greatly relieved by lukewarm baths and mild fomentations.

Edaphodonta (*ἔδαφος*, *a base*, and *ὀδὸν*, *tooth*). A group of fossil fishes from the green-sand chalk and tertiary strata, in which each upper maxillary has three dental columns; the premaxillary dental mass consisting of five vertical and slightly bent series of oblique and curved transverse plates; the median and largest series being strengthened by a supplementary dental column behind.

Eddas (Norse). The ancient collection of Scandinavian poetry in which the national mythology is contained. There are two Eddas: the older is believed to have been reduced to writing, from oral tradition, in Iceland, between A.D. 1060 and 1133. It was recovered and published in Denmark in 1643. The new Edda, supposed to have been composed 200 years after the former, is an abridgement of it, with a new arrangement of its parts. It was translated by Resenius in 1640, and is thence called the Resenian Edda. The authenticity of these monuments of an early age has been doubted in recent times; but the latest researches of critics (the brothers Grimm and others) seem to go far towards establishing it.

Eddoes. The tuberous stems of various *Aracea*, as *Colocasia esculenta*, *Caladium bicolor*, *violaceum*, &c., often eaten in tropical countries.

Eddy (commonly referred to A-Sax. *Edeas*, *breakwater*; but Mr. Wedgwood holds that it represents the old Norse *yda*, a whirlpool: *Dictionary of English Etymology*). The water of a stream or tide which, in consequence of striking against some obstacle, is thrown backwards, and runs in a direction opposite to that of the general current. More frequently, however, the term is used to denote the whirling or circular motion caused by the meeting of two opposite currents; and, in this sense, it is also applied to a similar motion of the atmosphere. [WHIRLPOOL; WHIRLWIND.]

Edentals, Edentata (from Lat. *e*, and *dens*, *tooth*). The name of an order of Mammals, including those genera in which the dental apparatus is more or less incomplete: the incisive teeth are almost always deficient. [BRUTA.]

Edge of Regression of a Surface. The curve generated by the successive intersections of the characteristics of a surface. The French equivalent, *arête de rebroussement*, appears to have been first used by Monge; in England, the synonymous term *cuspidal edge* is generally preferred. [CUSPIDAL EDGE and CHARACTERISTIC.]

Edict (Lat. *edictum*, from *edico*, *I speak out*).

An instrument signed and sealed to serve as a law. In ancient Rome the name was given to the ordinances of the magistrates, but especially of the two prætors, *prætor urbanus* and *prætor peregrinus*, who on their accession to office published *edicts* or rules for regulating the practice of their courts, as well as for their own guidance in the decision of doubtful cases. A jurisdiction, however, thus vague and arbitrary in its nature, being constantly abused, it was enacted by the Cornelian Law (a.c. 56) that the prætor of the year should be compelled to adhere to the spirit and letter of his first proclamation. The edicts of the preceding prætor were not binding on his successor. If the latter confirmed them, they were styled *edicta vetera* or *tralatitia*; in contradistinction to *edicta nova*, those framed by himself. [PÆTOR.] Under the emperor Hadrian, a digest of the best decisions of the prætors from the earliest times was made by Sylvius Julianus, collected into a volume called *Edictum Perpetuum*, or Perpetual Edict, ratified by the emperor and senate, and fixed as the invariable standard of civil jurisprudence. (Gibbon's *Roman Empire*, ch. xlv.)

The *Edict of Milan* was a proclamation issued by Constantine after the conquest of Italy (A.D. 313), to secure to the Christians the restitution of their civil and religious rights, of which they had long been deprived, and to establish throughout his extended dominions the principles of a wise and enlightened toleration.

The most famous edict of modern history is the Edict of Nantes, issued by Henry IV. in 1598, to secure to the Protestants the free exercise of their religion. This act, after continuing in force for nearly a century, was repealed by Louis XIV.; and, as is well known, its revocation led to a renewal of the persecutions and bloody scenes which before the issuing of this edict had been enacted against the Protestants. The depopulation caused by the sword was also increased by emigration. Above half a million of her most useful and industrious subjects deserted France, and exported, together with immense sums of money, those arts and manufactures which had chiefly tended to enrich the kingdom. About 50,000 refugees passed over into England; and there can be little doubt that their representations of the cruelties perpetrated by the king of France tended to excite the suspicion of the English against their own Roman Catholic sovereign, and in some degree accelerated the Revolution of 1688. [HUGUENOTS.]

In the French law, the term *edict* has a wide signification, being applied equally to the most momentous and the most trifling proclamations of the government.

Edingtonite. A mineral found in Dumbartonshire in small greyish-white translucent prisms, composed of silica, alumina, baryta, and water. Named after the discoverer, Mr. Edington.

Edition (Lat. *editio*, from *edere*, *to give out* or *publish*). This word denotes properly the (indefinite) number of copies of a work printed at one time, before the types are distributed by the compositor. Anyone who prepares for publication the writings of another is said to edit them, and is called the *editor*. In literary language, since the invention of printing, the *editor* of a work revises, adds notes, prepares for the press, &c. &c.; the *publisher* is the bookseller who negotiates the sale of the impression. Sometimes (but especially in classical works) the edition goes generally by the name of the printer or publisher, sometimes by that of the editor. Thus, we have the Aldine and Elzevir Classics, &c., the houses of Aldus and Elzevir having been concerned both in printing and publishing; while Bentley's *Horace*, Heyne's *Homer*, &c., are so denominated from the name of the *editor*. In Bibliographical works, *editio princeps* signifies the earliest printed edition of an author; *editio optima*, that which is generally regarded as the best, &c.

Edriophthalma (formed from Gr. *ἰσθαῖς*, *fixed*, and *ὀφθαλμός*, *an eye*). The name under which the Malacostracous Crustaceans with sessile eyes are grouped together.

Education (Lat. *educatio*). In its most extended signification, may be defined, in reference to man, to be the art of developing and cultivating the various physical, intellectual, and moral faculties; and may thence be divided into three branches—physical, intellectual, and moral education. This definition is by no means complete; but it is used merely as indicative of the manner in which this subject has generally been discussed. Under physical education is included all that relates to the organs of sensation, and the muscular and nervous system. Intellectual education comprehends the means by which the powers of the understanding are to be developed and improved, and a view of the various *branches of knowledge* which form the objects of instruction of the three departments into which we have divided education. Moral education embraces the various methods of cultivating and regulating the affections of the heart.

Eduction Pipes. The pipes in a steam engine through which the steam is led from the cylinder, after it has accomplished its work, through the escape valves to the condenser.

Edulcoration (Lat. *edulco*, *I purify* or *sweeten*). A chemical term applied to the cleansing of substances, especially pulverulent precipitates, by the repeated affusion of water, so as to remove all soluble matters, and render them free from taste and smell.

(Ger. *eal*). There are three species of eels indigenous to the British Isles—the Sharpnosed (*Anguilla acutirostris*), the Blunt-nosed (*A. latirostris*), and the Middlednosed (*A. medirostris*). The Sharpnosed is the best and commonest variety; the Blunt-nosed is a coarse and comparatively worthless fish, fierce, voracious, and filthy in its food, of an

EEL, ELECTRIC

offensive odour before it is cooked, and a repulsive flavour afterwards. The mode of procreation of eels has long been a doubtful question; but it seems now satisfactorily ascertained that they are produced after the manner of fish generally, namely from deposited ova, that they chiefly breed in brackish waters, and that the young fish (elvers) ascend from the estuaries in countless thousands, migrating from the sea, and overcoming extraordinary difficulties in their passage up rivers. Their migrations principally take place in spring and early summer; but of the myriads that ascend, comparatively few escape the enemies that beset them on their journey. In some salmon rivers, the pools are in a perfect boil with the rising of the salmon at the small eels; and cartloads of the fry are sometimes collected for sale in Cornwall and Devonshire, and made into cakes, or even used as manure, or given to the pigs. But although eels descend from rivers or lakes for the purpose of depositing their ova in salt or brackish water, there can be little doubt that they may also breed in waters having no communication with the sea. This seems to have been experimentally verified, though it has been suspected that in these cases the fish may have availed themselves of some overland communication with an adjacent river, making their way through moist meadows or shallow watercourses.

The high repute in which eels were held by the ancients is well known: they were deified by the Egyptians, and invoked by the ancient Greeks as 'the Helen of the dinner table,' because every guest strove like Paris to supplant his neighbour, and keep her for himself; and the Russians kept them in their fishponds ready at hand for the table. With us at the present day eels are duly appreciated; the London market is chiefly supplied from Holland, and it appears from an estimate made by Mr. Mayhew (*London Labour and London Poor*) that between nine and ten millions of eels are annually sold at Billingsgate, amounting in weight to more than 1,600,000 lbs., of which above one-fourth is sold by the costermongers chiefly for the sustenance of the working classes. The price of the eels required for the Billingsgate trade amounts to the annual sum of more than 13,000*l*. The *Conger Eel* (*Conger vulgaris*) differs little in structure, but attains enormous dimensions. Specimens weighing from 50 to 130 lbs., measuring more than ten feet long and eighteen inches in circumference, have occasionally been captured. The flesh of the conger is tough and disagreeable; yet it is not only sometimes eaten, especially in soup, but in the Isle of Man it may be said to take the place of the poor man's pig. It is caught there in abundance, and is split, salted, and dried. (See *Quarterly Review*, 1864, and the authorities there quoted.)

Eel, Electric. [*Gymnotus*.]

Effect (Lat. *effectus*). In the Fine Arts, that quality in works of art whose nature is to give particular efficacy to other qualities,

EGG

so as to bring them out and to attract the eye of the spectator.

Errort. [*Kuerrro*.]

et. A Turkish word signifying *lord* or *superior* (from the Greek *αἰετός*), applied to legal, ecclesiastical, or other *civil* functionaries, in contradistinction to *aga*, the name by which high *military* personages are designated. [*Russ Errandir*.]

Effervescence (Lat. *effervesco*). The escape of gaseous matter from liquids, as in the act of fermentation. All liquids from which bubbles of gas rapidly escape, so as to resemble boiling, are said to *effervesce*.

Effigy (Lat. *effigies*). In Painting and Sculpture, the representation of an individual.

Efflorescence (Lat. *effloresco*). The spontaneous crumbling down of transparent crystals in consequence of their loss of water.

Effluvium (Lat. *a flowing out*). The vapours arising from putrefying matters.

Effusion (Lat. *effusio*, *a pouring out*). In the escape of a fluid from the vessel containing it; thus when the chest is wounded, blood may be effused into the cavity of the pleura, and in injuries of the head blood may be effused upon the brain, when death almost inevitably ensues.

Egeran. A variety of Garnet found near Eger in Bohemia.

Egeria (Lat.). One of the small planets between Mars and Jupiter. It was discovered at Naples on Nov. 2, 1850, by Dr. de Gasparis (who had previously discovered Hygeia and Parthenope), and is the thirteenth of the group in the order of discovery. [*PLANET*.]

Egg (A.-Sax. *æg*; Ger. *ei*). The ovum of birds and oviparous animals. The changes which the hen's egg undergoes during incubation have been described by Sir E. Home in the *Phil. Trans.* for the year 1822 (page 339), and illustrated by a beautiful series of plates after Bauer's drawings: the same volume also contains a valuable paper by Dr. Prout on the same subject, but chiefly in reference to the chemical changes of the egg during that process. The specific gravity of new-laid eggs at first rather exceeds that of water, varying from 1,080 to 1,090; but they soon become lighter, and swim on water, in consequence of evaporation through the pores of the shell. When an egg is boiled in water and suffered to cool in the air, it loses about 32 hundredths of a grain of saline matter, together with a trace of animal matter and free alkali. The mean weight of a hen's egg is about 875 grains, of which the shell and its inner membrane weigh 93·7 grains, the *albumen* or white 529·8 grs., and the yolk 251·8 grs. The shell contains about 2 per cent. of animal matter and 1 per cent. of the phosphates of lime and magnesia, the remainder being carbonate of lime with a trace of carbonate of magnesia. When the yolk of a hard-boiled egg is digested in repeated portions of strong alcohol, there remains a white residue having the leading characters of albumen, but containing phos-

EGG-PLANT

phorus in some peculiar state of combination : the alcoholic solution is yellow, and deposits a crystalline fatty matter, and when distilled leaves a yellow oil. The albumen of the egg contains sulphur. The use of the phosphorus is to yield phosphoric acid to form the bones of the chick ; but the source of the lime with which it is combined is not apparent, for it has not been detected in the soft parts of the egg, and hitherto no vascular communication has been discovered between the chick and the shell.

The trade in eggs is of great value and importance ; the number of eggs imported into this country from various parts of the Continent greatly exceeds one hundred millions ; and there is every prospect of a steady increase.

Egg-plant. The Aubergine *Solanum esculentum*, the fruits of which resemble hens' eggs.

Eglantine (Fr. *églantier*). The old English name of the *Rosa rubiginosa* or Sweet-brier Rose ; also *Rosa Eglanteria*. The term is improperly applied by Milton to the honeysuckle.

Egyptian Architecture. [ARCHITECTURE.]

Egyptian Bean. The fruit of the *Nelumbium speciosum*, which has been regarded as the forbidden bean of the disciples of Pythagoras.

Egyptian Pebble. A species of Jasper found in roundish pieces, scattered over the surface of the Desert, between Cairo and the Red Sea.

Eider Duck. The species of duck tribe so called is one of the largest and most valuable of the *Anatida*, and, from certain modifications of the beak and sternum, constitutes the type of a subgenus, called *Somateria*. The common eider (*Somateria mollissima*) frequents in great numbers the Orkneys, Hebrides, and Shetland isles. It is defended from the cold of the dreary northern coasts by the development of an unusual quantity of the finest down beneath the dense exterior plumage, which is equally well adapted to form an impenetrable barrier to the wet. The down of the eider constitutes its chief value, as it combines with its peculiar softness, fineness, and lightness so great a degree of elasticity that the quantity of this material which might be compressed and concealed between the two hands will serve to stuff a coverlet.

As the female plucks from her own body a quantity of her finest down to line her nest, the Orcadians avail themselves of this instinct, and take an early opportunity to rob the nest of both eggs and down. She then begins to lay afresh, and envelopes her eggs with another layer of down ; and if this be removed, the male is said to contribute his own down when the female can afford no more. Lastly, when the brood of ducklings is hatched, the nest is again visited and the down removed. Thus a considerable quantity of the valuable material furnished by the eider-duck is obtained independently of that which is plucked from the slaughtered birds. Besides the down and eggs, the islanders turn the skins and flesh of the

EL DORADO

eiders to profit ; while these birds cost them no expense, as they feed entirely on seaweed and other natural productions of the ocean.

Idiograph (Gr. *idios*, form ; *γραφω*, I describe). A copying instrument invented by Professor Wallace, of Edinburgh, by which copies of drawings are made, reduced, or enlarged in any proportion within certain limits. It answers the same purposes as the ordinary pentagraph, but is more convenient and accurate. The instrument was invented about 1821, and was first described in the *Transactions of the Royal Society of Edinburgh*, vol. xiii. ; it is also described in Wallace's *Geometrical Theorems and Analytical Formulae*, 1839.

Ikon Basilikê (Gr.). The title of a work, attributed to Charles I. ; but the authorship of this 'Portraiture of his Sacred Majesty in his Solitude and Sufferings' has been traced to John Gauden, bishop of Exeter, on evidence which Sir James Mackintosh pronounced to be conclusive.

Eisteddfod (Welsh, from *eistedd*, to sit). The assemblies or sessions of the Welsh bards were so termed. [BARD.] 'They were held, according to Pennant (*Tour in Wales*), at different places for the minstrels of their respective neighbourhoods ; at Caerwys, at Aberffraw in Anglesea, and Mathrawl in Powys. The judges were appointed by commissions from the Welsh princes, and after the Conquest from the English kings. The last was issued in 1568. But the Gwynnedigion and Cambrian Societies have lately revived the old custom ; and annual meetings for the recitation of prize poems, and for performances on the harp, are now held under the name of Eisteddfod.

Ejectment (Lat. *ejectio*, a casting forth). In Law, is a personal action in the form of trespass, in which a tenant for years claims damages for his expulsion from land demised to him ; and it became the usual form of trying questions of right to real property by a singular fiction—the party claiming land or its appurtenances not in his possession through the means of a fictitious tenant (the celebrated John Doe). This fictitious mode of proceeding was, however, abolished by the Common Law Procedure Act 1852 (15 and 16 Vict. c. 76), and a series of simple rules substituted for it. The effect of judgment for the plaintiff in ejectment is that he recovers the possession only of the land claimed, with or without costs, but not any particular estate or interest therein. As a general rule, therefore, a judgment in ejectment does not conclude the title, and an unsuccessful claimant can bring another action of ejectment.

El Dorado (Span. *the golden region*). The name given by the Spaniards in the sixteenth century to a country supposed to be situated in the interior of South America, between the rivers Orinoco and Amazon. After the Spanish conquest of Mexico and Peru, the most exaggerated accounts of the wealth and riches of the newly acquired territory were circulated and believed. A new region was fabled to exist far surpassing the wealth and splendour of Peru ;

expeditions were fitted out for the purpose of discovering it; and though all such attempts proved abortive, the rumours of its existence continued to be believed down to the beginning of the last century. The term has now passed into the language of poetry, in which it is used to express a land of boundless wealth, like the ancient Elysium or the Mohammedan Paradise.

Elæagnaceæ (Elæagnus, one of the genera). A natural order of shrubby arborescent Exogens inhabiting the entire northern hemisphere down to the equator, having leprous leaves, superior fruit, and apetalous flowers with a tubular calyx. They are distinguished from *Thymelacææ* by the ovule being erect; from *Proteacææ* by the valvate calyx, and the dehiscent fruit of the latter; and from *Santalacææ* by the superior ovary. The berries of some species are eaten in Persia and Nepal.

Elæis (Gr. *ἑλαια*, an olive-tree). The Oil Palm of Africa, *E. guineensis*, yields the celebrated palm oil so much used in this country in the manufacture of candles. This tree is a native of west tropical Africa, where it occurs in great numbers, yielding an enormous quantity of fruits, from the outer fleshy coating of which the oil is obtained by boiling in water and skimming off the oil as it rises to the surface. Its production and preparation are carried on solely by the negro population. The amount of palm oil imported to this country, in 1863, was nearly 800,000 cwt.

Elæolite (*ἑλαιον*, oil, and *λίθος*, stone). A name given to the coarse massive kinds of Nepheline which have a waxy or greasy lustre. It is of various shades of green, grey and red, and is a silicate of alumina, potash, and soda. It is found in zircon-syenite at several places in Norway; in the Ilmen mountains, and in North America. The pale-blue varieties are slightly opalescent, and are sometimes used for ring-stones.

Elæometer (Gr. *ἑλαιον*, and *μέτρον*, measure). An instrument for detecting the adulteration of olive oil.

Elæoptene (Gr. *ἑλαιον*, and *πτερός*, *inged*). The liquid portion of the volatile oils, when separated from the concrete, or crystallisable portion, which has been called *stearoptene*.

Elæidin (Gr. *ἑλαιον*). A fatty matter produced by the action of nitric acid upon certain oils, especially upon olive oil and almond oil.

Elæin (Gr. *ἑλαιον*). That portion of fat or oil which retains a liquid state at ordinary temperatures; it may be pressed out of hog's lard and other solid fats, and separated from oils by exposing them to cold and subsequent pressure. [OLEIN.]

Elæphrium (Gr. *ἑλαφρός*, light). A genus of *Amyridacææ* yielding some of the medicinal resins. Mexican Elemi is said to be furnished by *E. elemiferum*.

Elæps. A subgenus of viper. [VIPERA.]

Elæmotherium (Gr. *ἑλαμῖς*, a metal plate, and *θηρ*, a beast). The name of an extinct Pachydermatous animal, which forms the type of a new genus, characterised by the

laminated structure of its teeth, and intermediate between the horse and rhinoceros.

Elastic Bitumen. A variety of Bitumen found in soft masses (which sometimes become harder on exposure), of various shades of brown. It is flexible and elastic (whence the names *Elastrite* and *Mineral Caoutchouc*). It is met with at the Odin lead-mine, at Castleton in Derbyshire; at St. Bernard's Well near Edinburgh; at the coal mines of Montrelais in France, at Neufchatel, and in the Island of Zante.

Elastic Curve. In Mechanics, as originally defined by James Bernoulli, the figure which a thin horizontal elastic plate would assume if one end were fixed and the other loaded with a weight. The equation of the curve to rectangular coordinates, of which the origin is at the fixed extremity and the abscissa axis horizontal, is $y = b(3ax^2 - x^3)$, where b is a small quantity depending on the ratio of the attached weight to the elastic force of the plate whose length is a .

Elasticity (from Gr. *ἑλάνω*, I draw). In Physics, that property which certain bodies possess of recovering their primitive form and dimensions after the external force by which they have been dilated or compressed or bent is withdrawn.

The theory of elasticity must be deduced from some hypothesis respecting the constitution of matter. The simplest and most general view which can be taken of the subject is, that all matter is composed of indefinitely small parts or molecules acted upon by attractive and repulsive forces. From the combined action of these two forces result the different forms of matter with their varied physical properties.

This view of the constitution of bodies supposes that the molecules are not in contact, but at a certain distance from each other, which, though it is to be regarded as infinitely small in comparison of any distance appreciable by our senses, admits nevertheless of increase and diminution. When a body is in a state of rest, the opposite forces which any two of its contiguous molecules exercise on each other are in equilibrium. The energy of the forces also depends on the distance between the two molecules, or, in mathematical language, is a function of that distance. If the distance be increased within the limits of the action of the forces, both forces are diminished; and if the distance is diminished, both are increased, but not in the same proportion. If the interval at which the two forces balance each other be diminished, the repulsive force becomes stronger than the attractive force, and the two molecules are repelled from each other; on the contrary, if the distance be increased, the attractive force acquires the superiority, and the molecules are drawn towards each other.

Let us now suppose a solid body, of which all the molecules are in a state of equilibrium, to receive the impression of an external force. The operation of the force is to produce a change in the distances of the molecules at the

surface, in consequence of which the equilibrium is disturbed, and the molecules thrown into a state of vibration. This vibration is communicated to the interior molecules; and the body, under the action of the external force, undergoes a certain change of form. The molecules at the surface, which receive the impulse, transmit it to those in the interior of the body, and are reacted on by them with force. In this manner the action is propagated through the whole mass, until it is destroyed by another exterior force, or by the resistance of an obstacle to the motion of the body itself.

Elasticity is perfect when the body exactly recovers its primitive form, after the force by which it is bent or compressed or dilated has been removed, in the same time as was required for the force to produce the alteration. This perfect elasticity is, however, not found in any of the bodies of nature; the æriform fluids or gases are those whose elasticity approaches the nearest to it.

The principal phenomena of elastic bodies are the following: 1. That an elastic body (the elasticity being supposed perfect) exerts the same force in endeavouring to restore itself as that with which it was compressed or bent. 2. The force of elastic bodies is exerted equally in all directions, but the effect chiefly takes place on the side on which the resistance is the least. 3. When an elastic solid body is made to vibrate by a sudden stroke, the vibrations are performed in equal times, to whatever part of the body the stroke may be communicated. Thus, sonorous bodies always emit sounds of the same pitch; and the difference of the pitch depends on the greater or less frequency of the vibrations of the sonorous body.

Elasticity, Surface of. The central pedal of an ellipsoid. [**PEDAL SURFACES.**] The surface was so called by Fresnel (*Mémoires de l'Institut*, vol. vii.), who found its radii vectores to be proportional to the square roots of the elastic forces, in the directions of these radii, of the luminous ether around any point of a crystalline body. These radii vectores, therefore, are also proportional to the velocities with which waves are propagated whose ether-particles vibrate in directions parallel, respectively, to the radii vectores in question. By means of the elastic surface, therefore, we are enabled to explain the phenomena of double refraction, since the angle of refraction depends upon the velocity of the wave. On this subject the reader may be referred to Dr. Lloyd's *Elementary Treatise on the Wave Theory of Light*, London 1857.

Eliater (Gr. *ἐλάρηρ*, a driver). A Linnæan genus of Coleopterous insects, now the type of an extensive family of the Serricorn Coleoptera. The *Elatridæ* may be distinguished from the other Serricorn beetles by the presence of a strong, short, and often slightly curved spine, projecting from the posterior margin of the prosternum, and of a depression just above the origin of the second pair of legs adapted for the

reception of the preceding spine. An *Eliater* may be recognised on a distant view from the particular use to which it puts the above described sternal modifications. If a beetle be seen to fall upon its back, and instead of making the ordinary attempts to set itself upon its legs, bends its head towards its tail, raising this part, and then suddenly springing into the air, and repeating the action until it has fallen upon its feet, such a beetle may be recognised at once as a species of one or other of the numerous subgenera of the *Elatridæ*. This leap is due to the rebound occasioned by the sudden disengagement of the sternal spine from its socket. One of the species of *Eliater* proper (*Eliater noctiluca*) is the common fire-fly of the tropical parts of America. Its luminosity is emitted by two round convex yellow spots situated at the sides of the thorax. The *Elatridæ* generally are vegetable feeders; the larvæ devour decayed timber; the perfect insects feed on flowers or other soft and living parts of vegetables.

Elaters. In Botany, the loose spiral fibres that are contained, together with the sporules, in the conceptacles of *Jungermannia* and *Marchantia* &c.

Elatarium (Gr. *ἐλαρπιος*, driving away). This substance, commonly called *extract of elaterium*, is obtained from the fruit of the *Ecbalium agreste*, formerly called *Momordica Elatarium*, or Squirting Cucumber. This, if gathered a little before it ripens, and the juice gently expressed, deposits a green sediment, which is collected and dried. In the dose of from one-eighth of a grain to a grain, good elaterium operates as a drastic purge, bringing away from the bowels a large quantity of watery secretion; it is seldom prescribed except with a view of diminishing the collection of fluid in cases of dropsy.

ELATERIUM. In Botany, a term invented by Richard to denote that kind of fruit which is found in *Euphorbia*, consisting of three or more carpels, consolidated when young, but bursting with elasticity when ripe. A synonym of Cocum.

Elatinaceæ (Elatine, one of the genera).

An order of small insignificant water or marsh plants, belonging to the Rutal alliance of hypogynous Exogens, and of no particular interest or value.

Elavl. [ETRYLENA.]

Elbow (A.-Sax. *elboga*, *elboga*; Lat. *ulna*; Gr. *ὤλον*). The angle in each of the two cables by which a ship is moored, made by the intertwisting of those cables consequent on the swinging of the vessel. To form an elbow, one cable must cross the other cable, and then reach the ground on the same side as it leaves the ship's bow. [HAWSE.] Also a term for a sudden turn in a line of coast or course of a river.

Elbows. In Architecture, the upright sides which flank any panelled work, as in windows, below the shutters, &c.

Elcaja. An Arabian tree, the fruit of which is emetic, and is employed in an ointment for

ELDERS

the cure of the itch: it is the *Trichilia emetica* of botanists.

Elders. Certain laymen who, according to the constitution of the Presbyterian church, form a council of which the minister is the moderator, and discharge the functions of a spiritual court. They also assist the minister in the management of the concerns of the parish, attending to the interests of the poor, like the deacons of the primitive church. Among the Jews, elders were those persons most distinguished for age, rank, and wealth, who formed the council of the people. [PRESBYTERAS.]

Eleatic Philosophy. A system owing its origin to Xenophanes, a native of Elea (in Latin *Velia*), who lived about the year B.C. 530. The most celebrated of his followers were Parmenides and Zeno, also natives of Elea. The dialectical character of the principal systems of antiquity may be said to owe its existence to the Eleatics. The tendency of their speculations was the direct contrary of that which distinguishes the Ionic school. While the latter fixed their attention on outward nature, and strove to discover the laws which regulate its progress, Xenophanes and his disciples confined their thoughts to what they conceived to be the only objects of real knowledge—the ideas of God, or Being as it is in itself. The world of succession and change, which they designated under the title of *that which becomes* (*τὸ γινόμενον*), they held to be utterly vain and illusory; the very conception of change itself seeming to them to involve a contradiction. Time, space, and motion they regarded as mere phantasms, generated by the deceiving senses, and incapable of scientific explanation. They were consequently led to distinguish between the pure reason, the correlative of Being, and in one sense identical with it, and opinion or common understanding, the faculty which judges according to the impressions of sense. Parmenides, in particular, was the author of a philosophical epic, the two books of which treated respectively of these two modes of thinking. For a full account of all that can be gathered from remaining fragments of this rigid system of rationalism, the reader must consult the German writers on the subject; in particular Brandis and Ritter, in their histories of philosophy. Frequent allusion is made both by Plato and Aristotle to the Eleatic doctrines, the authors of which are mentioned by both those philosophers in terms of evident respect and veneration. Plato has made their system the subject of a whole dialogue, entitled the *Parmenides*; perhaps the most striking specimen of dialectic subtlety which Grecian philosophy affords. (Thirlwall's *History of Greece*, vol. ii. c. xii.; Grote's *History of Greece*, part ii. ch. lxvii.)

Elecampane. The vulgar name of the *Inula Helenium*. It is an aromatic bitter, and was formerly regarded as expectorant; whence the monkish line,

Inula campana reddit præcordia sana.

ELECTIVE GOVERNMENTS

A coarse candy, composed of little else than coloured sugar, is sold under the name of elecampane.

Elect (Lat. *electus*, *chosen*). Some functionaries are so termed during the period between their appointment and some act which is necessary to ratify it; as a bishop after election and before consecration.

Election. In Law, this term denotes that a man is left to his own free choice to take or do one thing or another; as, where a man has two forms of action by which he may recover his right, it is within his election to choose that according to which he will proceed; or where, as in some cases, he has an election between several parties, against any of whom he may prosecute his suit. Where there are coparceners of lands, on partition the eldest sister has the election.

ELECTION. In Theology, the choice made by God of certain individuals of the human race to enjoy peculiar privileges and blessings. In the Old Testament, election is spoken of as national, not individual. The later doctrine of the arbitrary election of certain persons to eternal life—something resembling which is attributed to the Basilidians, Valentinians, and other early heretics—cannot easily be traced in the writings of any father of the church before Augustine, who embraced it with ardour, but appears to have varied in his opinions respecting it. It is rigidly laid down in his treatise *De Dono Perseverantiae*. Calvin, in modern times, was its great reassertor, and declared: 'We were elected from eternity, before the foundation of the world, from no merit of our own, but according to the purpose of the divine pleasure.' (*Inst.* iii. c. 15, s. 6.) It became a fundamental article of belief in Calvinistic churches. The synod of Dort was expressly convened to vindicate the doctrines of election and predestination against Arminian tenets (1615). The language of the church of England, on this point, admits of a variety of interpretations; but during the prevalence of Calvinism in the higher clergy, and especially in the university of Cambridge, under Archbishop Whitgift, an attempt was made to define her tenets more strictly. The Lambeth articles, agreed to in 1595 by a portion of the clergy, assert that 'God from eternity hath predestinated certain men unto life, certain He hath reprobated.' But these articles were not ratified, and have no authority. [CALVINISM; PREDESTINATION.]

Elective Affinity. Signifies the order of preference, as it were, in which substances combine: thus, if nitric acid be added to a mixture of lime and magnesia, it will elect or choose to combine with the lime in preference to the magnesia. [AFFINITY, CHEMICAL.]

Elective Governments. Governments in which all functionaries, from the highest to the lowest, are chosen by the suffrages of a greater or less number of citizens. Of these the government of ancient Athens, and in modern times that of the United States, will serve as examples. When the functionaries of

ELECTORS

an elective government are chosen by a very great number, it is a democracy; and when by a comparatively small number, it is either an aristocracy or an oligarchy.

Electors (Lat. *elector*, a *chooser*; Ger. *chur-* or *kur-fürsten*). Those princes of the old German empire who had a voice in the election of the emperor. These were originally (A.D. 1256) seven; Montz, Trèves, and Cologne—ecclesiastical; Bohemia, Brandenburg, Saxony, and the Elector Palatine—lay; but to these Bavaria was added soon after their institution. In 1692 this dignity was conferred on the dukes of Brunswick-Lüneburg, who were afterwards styled electors of Hanover; and, at different periods during the last century, on the princes of Salzburg, Wurtemberg, Baden, and Hesse Cassel. But on the extinction of the German empire in 1806, the title of *elector* was merged in that of *king*, grand duke, &c. &c., by all the German states except Hesse Cassel, whose sovereign is still designated *elector*. The electors had various privileges, both general and special.

Electric Column. An electric instrument invented by De Luc, consisting of numerous alternating discs of silver leaf, zinc leaf, and paper. [ELECTRICITY.]

Electric Fishes. The species of the class *Pisces* are so called which have the power of discharging electric shocks; the most remarkable are the *Torpedo*, *Gymnotus* or electrical eel, and *Silurus*, or *Malapterurus electricus*.

Electric Light. The immediate source of this, as of other artificial lights, is heat, but the heat is produced from the force of electricity; hence the term *electric light*. The electricity is generally evoked by the chemical reaction of a metal and an acid, the combination being termed a *battery*. From opposite ends of the battery the opposite kinds of electricity are conducted by wires which are terminated by pencils of hard coke. When these pencils are brought within a short distance of each other, the opposing electric currents rush together to form again neutral electricity, and this act gives rise to an enormous amount of heat. The heat is even sufficient to ignite the intermediate stratum of air to a point at which it evolves light; but this amount of light is insignificant compared with that given out by the ignited ends of the coke pencils and by the particles of carbon which are thrown off by one of these pencils. From these ignited portions of coke emanate the rays constituting this most intense and beautiful of all artificial lights.

Electric Telegraph. [TELEGRAPH, ELECTRIC.]

Electrical Mel. [GYMNOTUS.]

Electricity. This term is derived from the Greek *ήλεκτρον*, *amber*, the substance in which the property of attracting light substances after friction was first observed.

This truly extraordinary power of matter, independent of the interest that always belonged to it, has of late years acquired much importance from its influence over chemical

ELECTRICITY

phenomena, and its connection with those of magnetism. When a clean glass tube is rubbed with the dry hand, or with a piece of silk, it first attracts and then repels any light substances—such as feathers, bran, or little pieces of paper—which are brought near it; a stick of sealing-wax rubbed upon dry flannel exhibits the same appearances, and, to a superficial observer, seems to be exactly in the same state as the glass; and they are said to be electrically excited. But, on more close examination, it is found that when light bodies are repelled by excited glass, they are attracted by excited sealing-wax, and vice versa, so that the glass and wax are said to be in *opposite electric states*; and hence the terms *vitreous* and *resinous* or *positive* and *negative* electricity. But these two states are always coexistent; thus when glass is rubbed by silk the glass becomes positive, but the silk becomes negative; and in the case of sealing-wax rubbed by flannel, the wax is negative, but the flannel is positive.

A similar excitation of electricity is seen in an infinity of other cases: as when we rub a cat's back with the hand, or when a piece of silk ribbon is drawn briskly through the fingers, or a sheet of paper rubbed with a piece of caoutchouc, or a metal rod with a silk handkerchief. These, and other extraordinary phenomena connected with them, are hypothetically referred to the presence of a peculiar form of matter called the *electric fluid*, which is supposed to appertain to all matter, but to become evident only when in redundancy or deficiency. When glass is rubbed with silk, the equilibrium of the electric fluid is disturbed, and the silk imparts electricity to the glass; hence the former, losing electricity, becomes *minus* or negative, and the latter, acquiring it, becomes *plus* or positive. This is commonly called *Franklin's theory*, having been proposed and defended by that celebrated electrician. Others have assumed the existence of *two fluids* as essential to the explanation of electrical phenomena; both equally subtle, elastic, and universally diffused, and each highly repulsive as to its own particles, and attractive to those of the opposite kind. Electrical quiescence is referred to the combination of these fluids, and their consequent mutual neutralisation; and electrical excitation is the consequence of either being free or in excess. It is supposed that they are separated by friction, and by all those other causes which give rise to the appearance of free electricity. Either of these hypotheses may be adopted as facilitating the explanation of electrical phenomena, and as conferring meaning on terms which would otherwise be unintelligible; of the two, the simpler, or that which refers the phenomena to one fluid, is perhaps the most generally applicable. Both are apparently equally consistent with facts; but the actual idea of any *fluid*, or form of matter, as the cause of electrical phenomena, is now utterly repudiated by all electricians.

There are two series of distinct phenomena

ELECTRICITY

presented by electrified bodies: the one seems to result from the accumulation of electricity upon the surfaces of bodies, and is commonly included under the term *electricity of tension*, these phenomena being well exhibited by the common electrical machine and its prime conductor. It affects all neighbouring bodies, and they are thrown by it into a polar electrical state by what is termed *induction*: it has a tendency to pass off in sparks through the air, or gradually to escape from points. The thunder storm furnishes a magnificent specimen of this state of electricity. The other state of sensible electricity is that exhibited by *electricity in motion*; as when a current of electricity is passing through a wire or other conducting medium; in this case a vast quantity of electricity may be concerned in the phenomena without any apparent intensity; but, whilst the current is continuous, it produces magnetic phenomena of a most extraordinary character; and, when the perfect conductor is broken by the intervention of certain other media, they suffer in some cases chemical decomposition, and in others become heated, and even ignited. The phenomena of electricity in motion are best exhibited by the voltaic apparatus.

In all electrical experiments, remarkable differences are observed in respect to the transfer of the electric fluid through different bodies—some, as the metals, allowing its free and nearly unimpeded passage through their substance, while others receive and retain it more superficially, such as glass, resin, and other substances, which exhibit attractive and repulsive powers when rubbed. Hence the division of bodies into *conductors* and *non-conductors*.

Many most important electrical phenomena depend apparently upon *induction*, a subject which has been ably studied by Faraday (*Phil. Trans.*). We shall here enter into such details only as are required to render some of the principal terms employed in discussing electrical phenomena intelligible.

If P + represent a metallic sphere in a highly positive electric state, and N P a metallic conductor in its vicinity insulated upon a glass stem; it will be found that the extremity N of N P is *negative*, whilst the other extremity P is *positive*, and that these

opposite electricities are greatest at the extremities of the conductor, and gradually diminish towards the centre line C, which is neutral. This extraordinary state of excitation in N P is entirely dependent upon the proximity of P +; for if P + be withdrawn, N P loses all appearance of electricity; and the degree of excitement in it is directly proportional to the extent to which P + is excited, and (within certain limits) to its nearness to N; so that fluctuations in the electricity of N P will be observed in proportion as P + is brought towards or removed from N, provided they are not brought into *contact*, and that no *spark* passes. These phenomena have been theoretic-

cally explained upon the supposition that the free electricity in P + disturbs the equilibrium of the neutral electricity of N P, and by repelling it from N to P leaves the former *minus* and the latter *plus*. Or, if we assume the existence of two electric fluids, then the free positive electricity of P + *repels* the positive fluid of N P and *attracts* its negative fluid, throwing it into an *electro-polar* state. If N P, instead of being insulated, be connected by its extremity P with the ground, the accumulation at P is prevented, whilst N retains its deficient or negative state; or, upon the other theory, the positive fluid at P is neutralised by a supply of negative fluid from the earth; and if, after having effected this by momentarily touching N P with the finger, we suddenly remove P +, the insulated conductor N P will be left with an excess of negative electricity.

It will be obvious from the above statement that when light bodies, especially if they be conductors, are attracted by electrified surfaces in their vicinity, they are thrown by induction into opposite electrical states; and when the hand is brought near the excited conductor of the electrical machine, it becomes negative, and remains so till the equilibrium is restored by the passage of a spark; which phenomenon is supposed to be the result of the combination of the two electric fluids.

Many important phenomena of electrical accumulation are explained by reference to the principles of induction, and among them the action of the *Leyden jar* or *phial*. A thin glass jar or bottle, A, is coated inside and out, to within three or four inches of its mouth, with some conducting substance (tinfoil, being especially convenient for the purpose, is generally used); and a metallic rod projecting a few inches from the aperture, and surmounted by a brass ball, B, communicates with the interior coating.

When the ball is applied to the prime conductor of the electrical machine, and the outer coating communicates with the ground, the interior acquires a positive and the exterior a negative charge; and on making a communication by means of a conductor between the inner and outer coatings, the electricities are annihilated with the production of a bright spark and explosion, and by a most disagreeable sensation, called the *electric shock*, if the body be made part of the *circuit*. When several jars are so arranged that their interior and exterior coatings are all separately connected, the assemblage constitutes the *electrical battery*.

In the common *electrical machines*, electricity is excited by the *friction* of the plate or cylinder of glass upon the cushions or rubbers; and the glass becomes positive, communicating the same state to the opposed conductor, generally termed the *prime conductor* of the machine; while the rubber becomes negative, and is sometimes connected with a second conductor.

The following figures represent the two common forms of the electrical machine. The first

ELECTRO-BALLISTIC

is the cylinder machine. B is the glass cylinder which is made to revolve upon its axis by the multiplying wheels F, C, the necessary friction for the electric excitation being produced by the cushion and silk flap D. AA are the positive and negative conductors: the latter, bearing the cushion, is adjusted as to its requisite pressure upon the cylinder by the screw at E. The conductors are

respectively supported and insulated by the glass pillars G G, which should be coated

with lac varnish; and the axis of the cylinder rests upon the pillars H H, which are also of glass. The second figure represents the plate machine, in which A is the prime conductor, borne by a stout glass stem which is attached to the frame of the machine. BB are the upper and lower pairs

of cushions, by which, together with the silk flaps CC, the necessary friction is obtained. E is the disc of plate glass which is made to revolve upon its axis by the winch, F. In this machine, as the cushions or rubbers are not insulated, the negative electricity cannot be separately accumulated or exhibited, as in the cylinder machine.

There are many other and highly important causes of electric excitation besides those above adverted to; such as contact of different metals [GALVANISM], chemical action [VOLTAIC ELECTRICITY], change of temperature [THERMO-ELECTRICITY], and magnetism [MAGNETISM and ELECTRO-MAGNETISM].

Electro-ballistic Apparatus. An instrument for determining by electricity the velocity of a projectile at any part of its flight. The projectile passes through a screen, thus breaking a current of electricity, and setting in motion a pendulum, which is arrested on the passage of the projectile through a second screen. The distance between the screens being known, the arc through which the pendulum vibrates measures the time due to the projectile's flight between the screens.

Electro-biology (Gr. *ἤλεκτρον*; *Bios*, life; and *λόγος*, description). A term recently applied to certain mental phenomena, supposed by some to be produced by various applications of Mesmerism to the human body.

Electro-chemistry. That branch of chemical science describing the especial applications of electricity as a chemical agent.

Electro-dynamics (Gr. *ἤλεκτρον*, and *δύναμις*, power). The phenomena of electricity in motion.

Electro-magnetic Clock. The discovery of the mutual relations of electricity and mag-

ELECTRO-MAGNETIC CLOCK

netism by Oersted in 1819, necessarily led to the construction of the *electro-magnet*; and amongst its numerous applications, that to *timekeepers* was perhaps one of the most obvious. A bar of iron of any required form may have any amount of magnetism conferred upon it by proper adjustments of an electric current; and inasmuch as the magnetic power ceases the moment that the electric current is discontinued, so we are enabled to render a bar of soft or pure iron a strong magnet at one moment, and at the next to withdraw all such force. It will be further obvious, that these magnets may be made and unmade at any distance, by an adequate extent of metal wire; so that at one and the same moment a magnet may be made and unmade at London and at Liverpool, and simultaneously, if we please, with the vibrations of the magnetic needle which announces the signals of the electric telegraph. And, of course, the magnet may be made alternately to lift and drop a weight, or to bend and release a spring, or to raise and depress a lever. Bearing these matters in mind, the principle of electric clocks will be intelligible, without entering into minute details respecting their varied mechanism.

There are several ways in which electro-magnetism has been applied to these purposes; one of the first consisted in fixing upon the arbor or axis of the seconds wheel of a clock a wheel or disc of metal, the circumference or edge of which was divided into sixty alternating divisions of metal, and of ivory or wood, the metal being a conductor, and the ivory or wood a non-conductor of electricity. A small platinum peg, or point, was kept in contact with this divided edge, so as, by the revolution of the wheel, to be alternately in contact with the conducting and non-conducting surfaces, and so connected with a voltaic series as alternately to admit and resist the passage of an electric current. In this way, supposing the clock in question to be keeping accurate time, one or more electro-magnets placed anywhere in the circuit of the conducting wire would be made and unmade at each succeeding second. Now, it is easy so to connect an electro-magnet with a lever, as to give motion to a wheel and axle, and to cause it to revolve so as to indicate seconds, and when in communication with a proper train of wheels, to move the minute and hour hands of a clock; and his secondary, or *electro-magnetic clock*, would of course be regulated in its movements by the alternating electric current derived in the way we have mentioned from the original time-keeper. Every clock, therefore, upon the circuit, would show the same time as that shown by the regulator; and in this way, one good regulator may be made to preside as it were over any number of electro-magnetic movements, each of which will indicate the same time.

Another form of the electro-magnetic clock that in which the pendulum is itself kept in

ELECTRO-MAGNETIC CLOCK

action by electro-magnetism, and through it the other movements of the clock are sustained; and this is effected either *directly*, as in Bain's clock, or *indirectly*, as in Shepherd's clock. In Bain's clock, the pendulum, at each vibration, moves a light slide by which the electric current is alternately completed and broken, and by which magnetism is alternately conferred upon and abstracted from a coil enclosed in a heavy hollow brass case or tube which constitutes as it were the bob of the pendulum, and on either side of which are the poles of two common or permanent bar magnets, which alternately attract and repel the coil of the bob, as it is magnetised and demagnetised by the alternate presence and absence of the electric current. These clocks have been kept in motion by electric currents derived from a zinc plate buried in damp earth, and so far, therefore, independent of the usual forms of a voltaic battery, in which the electricity is derived from the action of dilute sulphuric acid upon zinc.

Another form of electric clock is that invented and patented by Mr. Shepherd; the large clock at the Great Exhibition of 1851, in Hyde Park, was of this description. In this clock, electro-magnetism is the sole moving power, its force being employed, not only to give impulse to the pendulum and to propel the ordinary movement of the clock, but also to perform the striking of the hour, no auxiliary weights or springs being employed. The pendulum is so arranged as to make and break the electric circuit, and make and unmake a horseshoe magnet at each vibration. Each time that the magnet is made, it attracts its armature, which lifts certain levers; one of these is concerned in raising a weighted lever, and causing it to be held up by a latch or detent; the magnet is then unmade in consequence of the pendulum breaking the circuit, and its armature is released, when the pendulum lifts the latch and allows the weighted lever to fall, which, in falling, strikes the pendulum so as to give it a certain adequate impulse; then the circuit is again completed, the armature attracted, the levers moved, the weight raised and held by the detent; another vibration breaks the circuit and then releases the armature; the pendulum then raises the detent, the weight falls, and in falling its arm strikes the pendulum and gives it its impulse, and so on.

But the pendulum at each vibration not only makes and breaks the electric circuit which maintains its own action, but also, and simultaneously, that of another battery, of which the duty is to make and unmake the electro-magnets belonging exclusively to the clock or clocks which are upon this circuit. These electro-magnets act upon the extremes of one or more horizontal bar magnets so as alternately to attract and repel their opposed poles, which carry upon their axes the pallets, by the alternating motion of which to the right and left the ratchet-wheel is propelled

ELECTRO-MAGNETISM

onwards at the rate of a tooth each second; and the axis of this ratchet-wheel carries the pinion which moves the other wheels of the clock.

The circuit of the battery connected with the *striking* part of the clock, is only completed once in each hour, and is connected with an electro-magnet so arranged as by means of a proper lever to pull the ratchet-wheel attached to the notched striking-wheel one tooth forward every two seconds, and each tooth is accompanied by a blow on an electro-magnetic bell. The number of blows depends upon the notched wheel, the spaces in the circumference of which are adapted to the number to be struck; and when this is complete, a lever falls into the notch, and in so doing cuts off the electric current, which is not re-established through the striking electro-magnet till the completion of the next hour, when a peg upon the hour-wheel pushes the striking-lever forward so as to cause it to be depressed by a similar peg on the minute-wheel.

Electro-magnetic clocks are peculiarly fitted for large establishments where many dials, each indicating the same time, are required: the pendulum by which the whole series is controlled is placed in some safe and quiet place, and the only requisite precaution for maintaining them in order consists in careful attention to the conditions and functions of the voltaic apparatus, or source of the electric current. Smee's batteries, as they are called, consisting of amalgamated plates of zinc in proper connection with plates of platinum or platinised silver, and immersed in dilute sulphuric acid, or in sand moistened with that acid, are generally used; the number and dimensions of the plates or cells depending upon the extent of wire which the electrical current is required to traverse, and care being taken that the chemical action of the acid upon the plates is as small and feeble as is consistent with the object in view. These clocks are also importantly useful upon lines of railway, and for a variety of other purposes, more especially when some few difficulties attending their management and maintenance are overcome.

Electro-magnetism. When a current of electricity is traversing any substance, such for instance as a metallic wire, or when electricity is *in motion*, magnetism is at the same time developed. This fact was first observed by Professor Oersted of Copenhagen in 1819. If a magnetic needle be brought near a wire through which an electric current is passing, the needle will immediately deviate from its usual position, and assume a new one, dependent upon the relative position of the needle and the wire. On placing the electric wire *above* and parallel to the magnet, the pole next the negative end of the battery always moves to the west; and when the wire is placed *under* the needle, the same pole turns to the east. When the electric wire is on the same horizontal plane with the needle, no declination takes place; but the magnet shows a disposition to move in a vertical direction, the pole next the negative side of the battery being

ELECTRO-METALLURGY

depressed when the wire is to the west of it, and elevated when it is to the east.

The magnetic phenomena of a wire transmitting electricity are such as appear to depend upon the circulation of magnetism at right

angles to the electric current, so that if N P represent the wire transmitting a current of electricity in the direction of the horizontal darts, a current of magnetism will be established in the direction of the vertical dart, appearing to move round the axis of the electric current; hence the term *vertiginous* or rotary magnetism, applied to these phenomena; and hence the motion of the pole of the magnet round the electric wire, or of the electric wire round the pole of the magnet, when they respectively are so arranged as to be able to move freely in any direction. If a steel

needle be placed in contact with the electric wire, and parallel to it, it acquires opposite magnetisms upon its two sides; but if it be placed at right angles to the connecting wire, that is, to the electric current, it becomes polar, and permanently magnetic. If the electric wire be twisted into a spiral, and the steel needle placed within it (as in the cut), it is retained there, and becomes a more powerful magnet in consequence of the repetitions and direction of the electric and magnetic currents, as will be evident

from the annexed figure, where *a* represents a glass tube, with the wire *n p* conveying the electric current twisted round it; the darts at the ends of which show the ingress and egress of the electricity, and the transverse darts the direction of the magnetic current. If the cylinder round which the wire conveying the electric current is twisted be of steel, it becomes a permanent magnet; if of pure soft iron, it becomes a temporary magnet, so long as the electric current is in motion, and *s* and *n* are powerfully opposed poles. If the bar be bent, as in the annexed cut, a powerful horse-shoe magnet is obtained

when the ends P N of the insulated copper wire twisted round it are connected with the voltaic circle; a single pair of plates is sufficient for the purpose, but the effect may be enormously augmented by additional pairs

and by increasing the number of coils of wire round the bar.

Electro-metallurgy. The electro-chemical precipitation of the metals, as applied to various purposes in the arts. For a description of these processes, see Smee's *Elements of Electro-metallurgy*.

Electro-negatives. Those substances which in electro-chemical decompositions make their appearance at the *anode* or electro-positive pole. The term has reference to the mutual attraction of bodies dissimilarly electrical, and hence those which appeared to be attracted by the positive pole in the voltaic circuit were presumed to have an inherent *electro-negative* state.

ELECTROPHORUS

Electro-positives. Bodies appearing in electro-chemical decompositions at the *cathode* or electro-negative pole.

Electrode (Gr. *ἤλεκτρον*, and *ὁδός*, a way). The surfaces by which electricity passes into and out of different media have been called *electrodes*. They are also termed the *poles* of the voltaic battery or pile.

Electrolysis or Electro-chemical Decomposition (Gr. *ἤλεκτρον*, and *λύω*, I dissolve). The separation of the elements of a compound by the transmission of electricity.

Electrolytes (Gr. *ἤλεκτρον*, and *λύω*). Substances susceptible of direct decomposition by the action of the electric current; hence, also, the verb *electrolyse*, i. e. to resolve compounds into their elements by the agency of electricity. Faraday has shown that in many supposed cases of electrolysis, the evolution of elements is the consequence of a secondary action; the sulphur, for instance, which is thus evolved at the negative pole from sulphuric acid, is the result of the evolution of hydrogen at that pole; in all cases of true electrolytic action, sulphur appears at the positive pole.

Electrometer. This term has been applied indiscriminately to instruments detecting electrical excitation [*ELECTROSCOPE*], and to those which are calculated to measure differences in the amount of electrical force. In Coulomb's torsion electrometer, the force opposed to that of electricity is the resistance to twisting offered by an elastic thread. In Henley's quadrant electrometer, the electric force is measured by the amount of repulsion which it produces upon a pith ball attached to a straw suspended from the centre of a graduated arc. [*ELECTROMETER*.]

Electromotor or Electromotive Force. Terms applied to the development of electricity in voltaic arrangements.

Electron (Gr.). By this name the ancient Greeks denoted (1) amber and (2) a metallic substance consisting of four parts of gold and one part of silver. [*ELECTRUM*.]

Electrophorus (Gr. *ἤλεκτρον*, and *φέρω*, I carry). This instrument consists of a resinous plate (A), which may be made of equal parts of shell-lac and rosin, with a little Venice turpentine, melted and cast into a circular disc of somewhat less than an inch thick, and from six to ten inches in diameter; it should rest upon a metal plate or sheet of tinfoil: upon its upper

surface is placed a somewhat smaller brass plate (B), with a glass handle. When the resinous plate is *excited*, by rubbing it with a warm and dry flannel, and the metallic cover put down upon it, a spark of negative electricity may be drawn from it, and if it then be raised it affords a second spark of positive electricity. On replacing the cover, and again touching it, it gives a negative spark, and on again raising it a second positive spark, and these sparks thus obtained may be repeated any number of times, so that the instrument forms a useful and portable electrical machine: it well illustrates

ELECTROPOLAR

the phenomena of induction, and is elegantly applied to inflame a jet of hydrogen gas in Volta's inflammable air lamp.

Electropolar. [INDUCTION.]

Electroscope. Many instruments have been devised for the detection of feeble electrical charges: the simplest consists of two small pith balls suspended by fine wire or thread from one end of an insulated conductor: upon the principle that bodies similarly electrified repel each other, these diverge upon the reception of minute quantities of electricity. Two thin slips of gold leaf are also similarly applied; and, to prevent the influence of the agitation of the air upon them, they are suspended in any convenient way under a glass shade.

The other forms of electrometers generally act upon the same principle, being adjusted to the varying degrees of quantity and intensity.

Electrotint. An art by which drawings are made with any substance insoluble in the solution of sulphate of copper. When the design is completed, the plate is immersed in the solution, and a reverse made by the electro-coppering process [VOLTATYPE] ready for the printer.

Electrotype. An impression of a medal, or bas-relief, obtained by electric precipitation. [VOLTATYPE.]

Electrovital Currents. Two electric currents are supposed by some physiologists to move in the nerves of animals: the one external and cutaneous, moving from the extremities to the cerebro-spinal axis; the other internal, and proceeding from that axis.

Electrum (Gr. *ἤλεκτρον*). A natural alloy of gold and silver in the proportion of two of gold to one of silver. It is found in tabular crystals and imperfect cubes of a silver-white colour in Siberia, Norway, Transylvania, California, and some other gold-mining districts. [ELECTRON.]

Electuary. This term is generally applied to powders mixed up with syrup, so as to be of about the consistency of treacle. *Lentive electuary*, or confection of senna, is a celebrated preparation of this kind; it is constituted of powdered senna, coriander seeds and sugar, mixed with the pulp of cassia, prunes, and figs, and decoction of liquorice.

Eledone (Gr. *ἐλεδώνη*). A name applied by Aristotle to a genus of Malakia or Cephalopods having a single row of suckers on each arm, and without any musky odour; it is applied in modern zoology to the same genus.

Elegit (Lat. *he has chosen*). In Law, a writ of execution, which lies for one who has recovered debt or damages; or upon a recognisance in any court against one not able in his goods to satisfy the same, directed to the sheriff, commanding him to make delivery of the land belonging to the debtor, and all his goods except beasts of the plough. The creditor holding the land until satisfaction is termed tenant by *elegit*. [EXTENT.]

Elegy (Gr. *ἔλεγος*). The name given in modern

ELEPHIAS

times to a species of poetical composition of a mournful character. But though this signification of the term tallies with the etymology usually given (Gr. *ἔλγω*, and *ἄλγος*, to cry alas), the expression *elegy* among the Greeks and Romans had a much wider meaning. Thus among the former it embraced equally the warlike verses of Tyrtæus, the melancholy effusions of Mimnermus, and the aphorisms of Theognis and Solon; while among the latter it comprehended the miscellaneous themes of Ovid, Propertius, Tibullus, and Catullus.

Elements (Lat. *clementum*). The old philosophers applied this term to imaginary principles of matter; such as fire, water, earth, and air. The elements of the alchemists were salt, sulphur, and mercury. The term *element* is now used as synonymous with *simple body*.

ELEMENTS. In Astronomy, are the data necessary to compute the place of a planet, satellite, or comet. [SOLAR SYSTEM.]

Elemi. A resinous exudation, probably yielded by *Icica Icariba*, *Elaphrium elemiferum*, and *Canarium commune*. It yields a volatile oil on distillation. It is used in ointments, giving them a gently stimulating character, and adding to their visciditv. The compound *elemi ointment* of the Pharmacopœia is a good preparation of this kind, and resembles the *yellow basilicon* of old pharmacy.

Eleonchus (Gr. *ἑλεγχος*). [SOPHISM.]

Elephant, White. A Danish order of knighthood of great antiquity: the number of knights is limited to thirty, besides members of the royal family.

Elephantiasis. A disease affecting chiefly the legs and feet, which, becoming rough, scaly, and swollen, have been compared to the feet of the elephant: the skin gets thick, actuous, and insensible, and the limb occasionally attains an enormous size.

Elephas or **Elephant** (Gr. *ἐλέφας*). The generic name of the most gigantic of existing quadrupeds. They are characterised essentially by having grinders composed of alternating vertical plates of ivory, enamel, and cæmentum, and two tusks in the upper jaw: they are also the only living Mammalia which have a proboscis or trunk longer than the head. It is inferred from the structure of the skull that the extinct Mastodons, which have grinders of a more simple structure, also possessed a long proboscis; and accordingly Cuvier includes the genus *Elephas* and *Mastodon* in a particular family of Pachyderms called *Proboscidiæ*. Of the true genus *Elephas* there are two living and a greater number of extinct species. The Indian elephant (*Elephas indicus*, Cuv.) differs from the African species in its greater size, in the skull being higher in proportion to its length, and as having a more concave forehead. The Indian elephant has also comparatively smaller ears; the skin is of a paler brown colour; and it has four nails on the hind feet instead of three. The elephant will breed in confinement; its period of gestation is twenty months and some days. It brings forth one

ELETTARIA

young at a birth, which derives its nourishment from two nipples placed on the inner side of the setting in of the forelegs. The perpendicular height of the Indian elephant, measured from the top of the shoulder, has not been found to exceed ten feet six inches; the ordinary height is from seven to nine feet. The Indian elephant varies as to the length of the tusks; their ends only are visible externally in the females, and there is also a race (*Mooknah*) in which they are straight and short in the males. In other races the males have the tusks long and curved, especially in that called *Dauntelah*. The anecdotes of the docility, sagacity, and tenacious memory of the elephant are numerous and generally known. The characteristics of the African elephant may be inferred from the account of those of the Indian species. It is usual to describe it as having a forehead convex instead of concave; but the projection is caused by the nasal bones, which are higher placed than in the Indian species; and the true front is in reality concave in the African species, but in a less degree than in the Indian. The chief external character of the African elephant is his huge ears. It is a remarkable fact that no African nation has ever subdued the elephant, or made it available for any useful purpose. For an account of the fossil elephants, see *MAMMOTH*. The genus has been divided into three subgenera—*Loxodon*, *Stegodon*, and *Eulephas*.

Elettaria (*Elettaro*, the native name). This genus of *Zingiberaceae* yields Cardamoms. *E. Cardamomum* furnishes the Small or Malabar Cardamoms of commerce; while Ceylon cardamoms are said to be the produce of *E. major*. The seeds are used in this country for their cordial aromatic properties, which are due to a volatile oil; and in India they are chewed by the natives with their betel, and are used in bowel complaints.

Eleusine (so called from Eleusis, the home of the Eleusinian *Déméter*). A genus of grasses which furnishes one of the Eastern corn crops. In India, China, and Japan, *E. coracana* is much cultivated for its large farinaceous grain. It is one of the grasses having fingered spikes of flowers.

Eleusinian Mysteries. The secret religious rites performed every year in honour of Demeter (or Ceres) and Persephoné (or Proserpine) at the Attic town of Eleusis. [*MYSTERIES*.]

Elevation (Lat. *elevo*, *I lift up*). In Architecture, a geometrical representation of a building measured vertically in respect of the horizon; by the ancients it was called the *orthography*. It is only in this sense that it is technically used by architects; in general terms it is the height of the building above the ground.

ELEVATION. In Astronomy, the angular height or the altitude of a celestial object above the horizon. Thus, *elevation of the pole* denotes the arc of the meridian intercepted between the pole and the horizon.

ELEVATION. In Gunnery, the inclination

ELGIN MARBLES

of the axis of the piece above the object aimed at, to allow for the falling of the shot by reason of the force of gravity; it varies with the range.

ELEVATION. In Perspective, is sometimes used for the scenography, or perspective representation of the whole object or building.

Elevation Crater. A volcanic crater supposed to be formed by the upheaval of a mixed mass of lava and scoria already poured out in a series of horizontal beds. The result of elevation of such accumulations is assumed to be a bubble-shaped hill, such as may be found in all volcanic districts. The bubble thus thrown up is supposed to break at the top to allow of the escape of the explosive material and molten rocks within, and thus a deep cup-like depression (the crater) is left when the eruption is over and the erupting matter is exhausted.

This theoretical view of the formation of a volcano is opposed to the rationalistic view of most of the English geologists; namely, that the cone is the result of the material accumulated round the point of eruption, and has been ejected from the burning mountain in successive sheets of lava wrapping round each other. This latter view is most in accordance with the observed facts of the case.

Elevation of the Host (from Lat. *hostia*, a victim). In the ritual of the *Mass*, the lifting up of the elements immediately after consecration, for the adoration of the people.

Elevation of Rocks. As almost all rocks have been deposited, from suspension or solution in water, below the sea level, or else at a great depth beneath the surface of the solid earth, at some place where heat is able to act uniformly, they can only have been brought to their present position at some distance above the sea level by having been lifted up by some force acting from beneath. The elevation of rocks is therefore a subject of much controversy; but the reader must refer to the several articles that bear upon the considerations involved, for detailed notices. It is certain that the upheaval has not always been rapid and violent, but that it has required a very long period of time, and many concurrent causes. [*EARTHQUAKES*; *DESCRIPTIVE GEOLOGY*; *AXIS OF ELEVATION*; *VALLEY OF ELEVATION*; *ANTICLINAL AXIS*.]

Elevator. A surgical instrument for raising depressed portions of the skull.

Elfs (A.-Sax. *Elf*) or *Fairies*. Imaginary beings, honoured more particularly by the northern nations, in whose mythology they occupy a prominent place. They were divided into two classes—the good and the bad [*Demons*]; and their exploits have given rise to a multiplicity of delightful stories. [*FAIRIES*.]

Elgin Marbles. A collection of ancient bas-reliefs, statues, &c., principally derived from the ruins of the Parthenon at Athens, and now deposited in the British Museum. Mr. Harrison, a northern architect of great ability, suggested to Lord Elgin, in 1797, at the period of his nomination to the embassy at Constantinople, the removal of these celebrated

ELIMINANT

works; but it was not till some time after Lord Elgin's arrival that the ministers of the Porte allowed him to detach any portion of the marbles; and about eighty cases arrived in England in 1812. In 1816 the collection was purchased by the government, upon the recommendation of a committee of the House of Commons, for the sum of 35,000*l*. They are without question the finest productions of sculpture in the world; their author is known to have been Phidias, and they represent some of the mythological fables connected with the history of Athens and the religious processions of the times.

Eliminant. In Algebra. [RESULTANT.]

Elimination (Lat. *elimino*, *I put out*). In Algebra, the operation by means of which, from a given system of equations, another is deduced in which one or more of the original unknown terms or facients no longer appears. Thus a system of m homogeneous independent equations in m variables, or, what is equivalent, a system of m non-homogeneous equations containing $m-1$ unknown terms, cannot be satisfied by a common system of values of these variables unless a certain relation exist between the coefficients. Elimination leads to the discovery of this relation; and the function which, equated to zero, expresses the same is called the *resultant* of the system of equations. The resultant is one of the most important of algebraical functions; a few words, therefore, with respect to its formation are necessary. [RESULTANT.]

The resultant of a system of m linear equations is the determinant, of the m^{th} order, whose constituents in any line (or column) are the coefficients, in those equations, of one and the same variable. The elimination in this case is the simplest possible; to it the more complicated eliminations may frequently be reduced.

The *method of elimination by symmetric functions* will be best illustrated by considering two non-homogeneous equations $F(x)=0$ and $f(x)=0$, of the m^{th} and n^{th} degrees respectively. In order that these equations may be satisfied by a common value of x , it is obviously necessary and sufficient that the product should vanish of the results obtained by substituting in one of the functions F, f the several roots of the other equation. Thus if $a_1, a_2 \dots a_n$ be the roots of $f(x)=0$, then $F(a_1)F(a_2) \dots F(a_n)=R$ will be the resultant of the two equations. It is clearly a symmetric function of the roots of the second equation, and can consequently be expressed as a function of its coefficients. [EQUATION AND SYMMETRIC FUNCTION.] The degree of R in the coefficients of F is clearly equal to n , the degree of $f(x)$.

The modifications to be introduced in the case of two homogeneous equations in two variables, and the extension of the method to any number of equations, is sufficiently obvious. Theoretically, this method is the best, though in practice it is superseded by more expeditious ones.

Euler's method of elimination is based upon

ELIQUATION

the following analysis: If the two equations have a common factor, then the same result will be obtained, no matter whether we multiply the first equation by the remaining $n-1$ factors of the second, or the latter by the remaining $m-1$ factors of the first. Consequently, if we multiply the first equation by a function of the $(n-1)^{\text{th}}$ degree provided with n indeterminate coefficients, and the second equation by a function of the $(m-1)^{\text{th}}$ degree provided with m such coefficients, the resulting functions of the $(m+n-1)^{\text{th}}$ degree, each containing $m+n$ terms, must be identical; and by equating the coefficients of their like terms we shall obtain $m+n$ equations, which the $m+n$ introduced constants must satisfy. These equations will obviously be homogeneous and linear; their resultant, therefore, which is manifestly that of the given equations required, is at once obtained in the form of a determinant, as above explained. Another very convenient method for obtaining the resultant of two equations in the form of a determinant was invented by Prof. Sylvester, and called by him the *dialytic method* of elimination. The equations being homogeneous of the m^{th} and n^{th} orders respectively, the first is multiplied, successively, by

$$x^{n-1}, x^{n-2}y, \dots xy^{n-2}, y^{n-1},$$

and the second by

$$x^{m-1}, x^{m-2}y, \dots xy^{m-2}, y^{m-1}.$$

The result is a system of $m+n$ equations of the order $m+n-1$, from which the $m+n$ *different powers and products*, such as $x^{m+n-1}, x^{m+n-2}y$, &c., may be eliminated as from a system of linear equations, and the resultant obtained in the form of a determinant. The dialytic method may be extended to the elimination of three variables from three equations of the same order. (*Phil. Mag.* vol. xxi. 1842.)

Bezout's method of elimination leads often to simpler results. The following very concise statement of the method in the case of two equations of the same degree is due to Prof. Cayley. (*Crelle's Journal*, vol. liii. 1857.) If $F(x, y)$ and $f(x, y)$ have a common factor, then the equation

$$F(x, y)f(x', y') - F(x', y')f(x, y) = 0$$

can be satisfied whatever values x' and y' may have. A factor of this equation is obviously $xy' - yx'$, and may be divided out. The coefficients of the several powers and products of $x'y'$ in the quotient may then be equated to zero, and from the equations thus obtained the powers and products of x and y may be eliminated as in the dialytic method.

Bezout's method, differently enunciated, may be applied also to two equations of different degrees. (*Salmon's Higher Algebra*.) One of the most recent treatises on Elimination is by Faà de Bruno (*Théorie générale de l'Élimination*, Paris 1859). The elements of the subject, however, are given in several treatises on Algebra and the Theory of Equations.

Eliquation or Eliquation (Lat. *eliquatio*). The separation of two metals by fusion.

ELISION

Elision (Lat. *eliso*). In Grammar, the cutting off or suppressing of a vowel at the end of a word, for the sake of euphony or the measure of the verse. The use of the *elision* was confined chiefly to the languages of Greece and Rome.

Elisir (Arab.). A term applied in old Pharmacy to certain essences or tinctures: a mixture of an aromatic tincture with sulphuric acid was called *elixir of vitriol*. The alchemists applied the term *elixir* to various solutions employed in the art of transmutation.

Ell. [**DEER**.]

Ell (Dutch *eln*, Fr. *aune*, Lat. *ulna*, Gr. *ἄλυν*). A measure of length adopted from the length of the forearm. The English ell is 3 feet 9 inches, and the Flemish 27 inches in length.

Ellagic Acid. An acid obtained by Braconnot from gall nuts, and differing from the gallic acid: the term is derived from the word *galle*, reversed. It is a grey crystalline powder, insoluble in water, but soluble in the alkalies. It is contained in the intestinal concretions known as *Oriental Bezoars*.

Ellipse (Gr. *ἐλλειψις*, *defect*). One of the conic sections, obtained on cutting a cone by a plane passing obliquely through its opposite sides. [**CONIC SECTIONS** and **QUADRIC**.]

We here subjoin one or two properties of the ellipse which lead to methods of describing the curve mechanically.

If two points F and F' be given in a plane, and a point D be conceived to move around them in such a manner that the sum of the two distances DF and D F' is always the same, the point D will describe upon the plane an ellipse ADB. The points F and F' are the *foci* of the ellipse; and the point C, which bisects the distance between the foci, is its *centre*. The line AA' is the *major or transverse axis*; and B B', which passes through the centre, and is perpendicular to AA', is the *minor or conjugate axis*.

The extremities of the axes are the *vertices*, and the double ordinate at either focus is called the *parameter* or *latus rectum*. If *a* and *b* denote the major and minor semi-axes, and *p* the parameter, the equation of the curve, taking the vertex A as origin, is

$$y^2 = px - \frac{p^2}{a^2} x^2;$$

that is, the square of the ordinate is less than, or differs in *defect* from, the rectangle under the parameter and abscissa. The term *ellipse* took its origin in this property. Referred to the centre as origin, the equation of the ellipse is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

Its polar equation, referred to the focus F as pole, is

$$r = \frac{a(1-e^2)}{1+e \cos \phi},$$

ELLIPTIC FUNCTIONS

where $e = \frac{CF}{CA}$ is the *eccentricity*, and $\phi = D F H$

the *anomaly*. Another useful auxiliary angle, which may frequently be employed with advantage in questions connected with the ellipse, is the *eccentric angle* θ , which is determined by the relations

$$x = a \cos \theta, y = b \sin \theta,$$

where the origin is supposed to be at the centre.

If a moving or generating circle roll along the concave circumference of a fixed circle in the same plane, and the radius of the former be half that of the latter, any given point in the plane of the generating circle, within or without it, will describe an ellipse. This very remarkable property of the ellipse, by which the curve is shown to be a hypotrochoid, has been applied to the construction of instruments for describing an ellipse by continued motion. (Wallace's *Conic Sections*.) [**ELLIPTIC COMPASSES**.]

The area of the ellipse is expressed by $\pi a b$, where $\pi = 3.14159$, and its whole periphery by the series

$$2\pi \left(1 - \frac{1}{2}e^2 - \frac{1 \cdot 3}{2^2 \cdot 4}e^4 - \frac{1 \cdot 3 \cdot 5}{2^2 \cdot 4^2 \cdot 6}e^6 - \frac{1 \cdot 3 \cdot 5 \cdot 7}{2^2 \cdot 4^3 \cdot 6^2 \cdot 8}e^8 \&c. \right)$$

where the major semi-axis is supposed to be unity, and e is the eccentricity, which in this case is equal to $\sqrt{1-b^2}$, if b be the minor semi-axis.

Ellipsoid. One of the surfaces of the second order, which is cut by every plane in an ellipse. It is symmetrical with respect to three rectangular axes $2a, 2b, 2c$, and has for its equation, referred to these axes,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Its numerous, remarkable, and very important properties are given in every good treatise on Coordinate Geometry. [**QUADRIC**.]

Ellipsoid of Revolution, called also **spheroid**. The surface generated by the rotation of an ellipse around one of its axes. The spheroid is said to be *prolate* or *oblate*, according as the axis of revolution is the major or minor axis of the ellipse.

Elliptic Compasses. An instrument for describing an ellipse by continued motion. [**ELLIPSE**.] Various contrivances for effecting this purpose are described in the *Exercitationes Mathematicae* of Schooten.

Elliptic Coordinates. [**COORDINATES**.]

Elliptic Cylinder. A surface generated by a line sliding, parallel to itself, along an ellipse. An elliptic cylinder may be considered as an oblique cylinder on a circular base. [**CYLINDER**.]

Elliptic Functions. Inverse functions of an elliptic integral. They bear the same relation to the latter as trigonometrical functions do to inverse trigonometrical ones, and exponential functions to logarithmic ones. Thus the amplitude ϕ of an elliptic integral u of the first species [**ELLIPTIC INTEGRAL**] being regarded as a function of u and of its modulus k , any trigonometrical function of ϕ is termed an

elliptic function, having the argument u and modulus k . In this point of view, ϕ is usually expressed by the symbol $am.(u, k)$, and the elementary elliptic functions $\sin \phi$, $\cos \phi$ and $\sqrt{1 - k^2 \sin^2 \phi}$ are denoted by the symbols $\sin am.(u, k)$, $\cos am.(u, k)$, and $\Delta am.(u, k)$. The elliptic functions $\tan am.(u, k)$, $\cot am.(u, k)$, $\sec am.(u, k)$ and $\operatorname{cosec} am.(u, k)$ can, of course, be obtained from the first two by mere division. The advantages to be gained by the introduction of elliptic functions into analysis appear to have been first recognised by Abel. They obviously include both trigonometrical and exponential functions. Trigonometrical functions are, as is well known, *periodic*, the *period* or periodic interval being real and equal to 2π . Exponential functions are also periodic, but their period is imaginary, and equal to $2i\pi$, where $i = \sqrt{-1}$. Elliptic functions, as might be at once anticipated, are *doubly periodic*, in the sense of having a real, as well as an *imaginary period*.

Elliptic Integrals. It is well known that every integral of an algebraic expression which involves no higher irrationality than the square root of an integral function of the second degree can be expressed in finite form by means of algebraical, inverse trigonometrical, and logarithmic functions. This is no longer the case, however, when, under the radical sign in the expression to be integrated, occurs an algebraic function of the third or fourth degree; the integral is then said to be *elliptic*, since in the rectification of the ellipse such integrals present themselves. If under the radical sign a function of a higher degree than the fourth occurs, the integral is called *hyper-* or *ultra-elliptic*. The most general form, therefore, of an elliptic integral is

$$\int f(x, R) dx,$$

where f denotes any rational algebraic function, and

$$R = \sqrt{a + bx + cx^2 + dx^3 + ex^4},$$

d and e being coefficients which do not both vanish. This integral, however, can always, by suitable substitutions and reductions, be subdivided into others, of which those which are not expressible by algebraic, inverse trigonometrical, or logarithmic functions can be made to assume one of the three following *canonical forms* :—

$$\int_0^x \frac{dx}{\sqrt{1 - k^2 \sin^2 \phi}}, \quad \int_0^x dx \sqrt{1 - k}$$

and

$$\int_0^x \frac{dx}{(1 + n \sin^2 \phi) \sqrt{1 - k^2 \sin^2 \phi}}.$$

Legendre, who first accomplished this reduction, and thus founded the theory of elliptic integrals, called these integrals respectively elliptic integrals of the first, second, and third species, and represented them, respectively, by the symbols

$$F(\phi, k), E(\phi, k), \Pi(\phi, k, n).$$

The quantity k , which is always less than unity, is called the *modulus*, and in the third integral n , which may be real or imaginary, is termed the *parameter*. The best works on the subject are Legendre's *Exercices de Calcul Intégral*, Paris 1811, and *Traité des Fonctions Elliptiques*, Paris 1832; Abel's *Œuvres Complètes*, Christiania 1839; Jacobi's *Fundamenta Nova Theoria Functionum Ellipticarum*, Regiomonti 1829; Briot and Bouquet's *Théorie des Fonctions doublement périodiques*, Paris 1859; and Durège's *Théorie der Elliptischen Functionen*, Leipzig 1861.

Elliptic Paraboloid. A surface of the second order, whose plane sections are either ellipses or parabolas. [QUADRIC.] Its equation can be reduced to the form

$$s = \frac{x^2}{a} + \frac{y^2}{b},$$

where a and b are positive magnitudes. The coordinate planes here coincide with the *principal* planes of the surface, the origin being at its vertex. All planes through the s axis cut the surface in parabolas; all planes perpendicular to that axis either cut the surface in ellipses or do not meet it at all. When $a = b$ the surface becomes a *paraboloid of revolution*, generated by the rotation of a parabola around its principal diameter or axis.

Elliptic Point. A point on a surface at which the indicatrix is an ellipse. Such a point is always a *conjugate* point of the curve in which the tangent plane intersects the surface; that is to say, the tangents to the section through this point (inflectional tangents of the surface) are always imaginary. [INDICATRIX.]

Elliptic Polarisation. [POLARISATION OF LIGHT.]

Ellipticity of the Terrestrial Spheroid.

A term used by Clairaut, and other writers on the figure of the earth, to denote the deviation of the earth's form from that of a sphere. Clairaut employed the term to denote the difference of the two axes divided by the smaller: most writers understand by it the difference of the axes divided by the greater. Thus, let a be the equatorial diameter, b the polar diameter, e the ellipticity; then $e = \frac{a - b}{a}$, whence $b = a(1 - e)$.

Elm (Lat. *ulmus*; Dutch, *olm*). A valuable genus of trees, confined to the colder parts of the northern hemisphere, but common to both the Old and New World. Most of the species are trees of considerable size, and produce a timber useful for many common purposes in which great strength and durability are not required; but some of them are small bushes of no known value. In Great Britain there are several species in a wild state, the most valuable of which are called the *Welsh*, the *Hertfordshire*, the *Huntingdon*, and the *smooth-leaved*; in other countries of Europe and Asia many peculiar species exist. The Elm is valued for the rapidity of its growth, its hardness, and its capability of thriving in poor soil unfit for allage.

ELMO, FIRE OF ST.

Elmo, Fire of St. A name given to the meteor known as CASTOR AND POLLUX.

Elocution (Lat. *elocutio*). Signified originally the art of choosing and adapting words and sentences to the ideas to be expressed; but it is more frequently employed to denote the right management of the voice, countenance, and gesture in speaking; in which sense it is synonymous with what is termed a *good delivery* or *pronunciation*. [DECLAMATION; ELOQUENCE.]

Éloge. A term applied in France to the panegyric orations pronounced in honour of illustrious deceased persons, and particularly of members of the Royal and other academies. Formerly the secretaries of the various French literary institutions used to compose and pronounce the *éloge*; but this duty is now performed by the new member elected in the room of the deceased.

Elongation (Lat. *e*, and *longus*, *long*). In Astronomy, the apparent angular distance of a planet from the sun. The greatest elongation of Mercury amounts to about 28½°, and that of Venus to about 47° 48'. With regard to the superior planets, the elongation may have any value from 0 to 180°.

Eloquence (Lat. *eloquentia*). The art of throwing the thoughts in the most suitable expressions, in order to produce conviction or persuasion. In its primary signification, eloquence (as indeed its etymology implies) had reference to public speaking alone; but as most of the rules for public speaking are applicable equally to writing, an extension of the term naturally took place. The influence exercised by speakers in the Homeric poems, is sufficient evidence of the enormous interval, which separated the Achæans (of a time long preceding the rise of contemporary history) from the immovable intellect of the Asiatic. Nestor and Odysseus could not be valued by a people incapable of governing themselves. But though, from time to time, there arose in Greece many distinguished writers upon eloquence, it does not appear that the practice of the art was systematically combined with the theory for public purposes till the time of Pericles, who was distinguished at once as a general, a statesman, and an orator. In the succeeding age arose the school of rhetoricians, or sophists, as they are called, who endeavoured to graft upon eloquence the subtleties of logic. (Grote's *History of Greece*, part ii. ch. xlvi.) Among the earliest and most eminent of this school were Gorgias, Isocrates, and Isæus, of whose publicly delivered orations ten are still extant. It was in this age that Grecian eloquence attained its highest perfection by the genius of Demosthenes. After this period, it declined rapidly; and though in the following ages there flourished among others Hæmægoras, Athenæus, Apollonius, Cæcilius, and Dionysius, their names have been almost without exception rescued from oblivion by a work which may be regarded as the last expiring ray of Grecian eloquence—the treatise of Longinus on the Sublime.

ELOQUENCE

At Rome, even so late as the year of the city 592, when, by the industry of some Greeks, the liberal arts began to flourish there, the senate passed a decree banishing all rhetoricians from the country. But a few years afterwards, when Carneades, Critolaus, and Diogenes were sent as ambassadors from Athens to Rome, the Roman youth were so charmed with the eloquence of their harangues, that the study of oratory formed thenceforth a branch of a liberal education. Men of the highest rank were now seen teaching and learning the art of eloquence; and such was the impetus given to this study, that it made the most rapid advances, and was at last crowned by the appearance of Cicero. That many illustrious orators existed at Rome prior to the age of Augustus, we learn from the work of Cicero, *De Claris Oratoribus*. In the succeeding ages of the Roman empire, the despotic character of the government checked the growth of the rhetorical art; but the names of Tacitus, Quintilian, and Pliny are an earnest of what might have been achieved had circumstances permitted the development of their talents.

During the middle ages, the theory of eloquence formed part of the scholastic study, as may be seen from the old doggerel hexameter, which served to fix the monastic studies in the memory—

'Gramm. (Grammaticæ) loquitur; Dia. (Dialecticæ) vera docet; Rhet. (Rhetoricæ) verba colorat.'

The history of eloquence in our own country brings before us the names of many great men who in former times directed the resolutions of our parliament; but no pains were taken to preserve their speeches. The orations of Chatham, Pitt, Burke, Fox, and Sheridan have experienced a better fortune; but the power of words has been felt in every stage of English history, as it can only be felt in countries which are constitutionally free or struggling towards freedom.

The little opportunity afforded for a display of forensic or senatorial eloquence by the different governments of Germany has almost entirely checked its growth in that country; and the same remark is applicable to Italy, Spain, and Portugal; all of which, however, have been rich in the eloquence of the pulpit. The only two countries in the world whose orators can be put in competition with those of Britain, are France and America. To the pulpit oratory of the former, the illustrious names of Bossuet, Bourdaloue, and Massillon have given enduring celebrity; while the popular character of their respective institutions has formed a host of forensic and senatorial speakers worthy a prominent place among the orators of ancient and modern times.

The elements of eloquence are usually comprised under the four following divisions: *invention*, *disposition*, *elocution*, and *delivery*. The first has reference to the character of the thoughts or ideas to be employed; the second, to their arrangement, usually called the *parts* of a discourse, consisting of the *Exordium* or

ELUTRIATION

INTRODUCTION, the NARRATION, the PROPOSITION, PROOF or REFUTATION, and the PERORATION [see these terms]; and the third and fourth have respect to words, style, utterance, action, &c.

The Greeks divided discourses according to their contents, as relating to precept (*λόγος*) manners (*ἥθος*), and feelings (*πάθος*). The Romans distinguished three kinds of eloquence, the *demonstrative*, occupied with praise or blame, and addressed to the judgment; the *deliberative*, which acts upon the will by persuasion or dissuasion; and the *judicial* or *forensic*, which was used in defending or attacking—a division originally laid down by Aristotle, *De Rhetorica*. In our own times, a division somewhat similar has been made; and the bar, the senate, and the pulpit are the three grand theatres for the exhibition of oratory.

It is not unfrequently urged that, in modern times, eloquence has not been invested with so much importance, or cultivated with so much care, as among the ancients. For the cause of this alleged inferiority of modern eloquence, no satisfactory reason has been hitherto assigned, and even Hume has confessed his inability to solve the problem. It is important, however, to mark the difference in the means employed in ancient and modern times to gain the consent of the audience. In the former, the most violent and passionate expressions, accompanied by what Cicero calls the *supplicio pedis*, and the *percussio frontis vel femoris*, were not only admissible, but were even necessary, in order to produce an effect upon the audience. At the present day, such violence of gesture, except on the stage, would excite nothing but laughter; and the fact that those orators are now more esteemed who aim at convincing the understanding than at captivating the feelings, must greatly modify the character and style of national oratory. (For the causes which specially stimulated the growth of rhetorical science at Athens, see Grote's *History of Greece*, part ii. ch. xli.)

Elutriation (Lat. *elutrio*, *I cleanse*). The separation of substances by washing them in large quantities of water, so that the heavier particles fall to the bottom, and the lighter ones, remaining some time suspended, are gradually deposited in a finely divided state.

Elvan. In Mining, a Cornish name for certain veins or dykes of porphyritic rock often crossing the direction of metalliferous veins, and interfering with them.

Elymus (Gr. *ἐλυμος*, *a sheath*). This genus of grasses furnishes one of the plants, *E. arenarius*, which are useful for binding together the loose sandy parts of the coast, which it does by means of its long creeping roots. It is otherwise of little importance, being extremely coarse in its herbage.

Elysium or the **Elysian Fields** (Gr. *ἑλύσιον πεδῖον*). In Mythology, the region to which the souls of the virtuous were said by the poets to be transported after death. They

EMANANT

are variously represented as part of Hades, or islands situated in the Western Ocean beyond the Columns of Hercules. The enjoyments of the blessed spirits in this abode were held to consist in the same pursuits that were their delight on earth, carried on in a calmer and happier climate. (*Odys.* iv. 563; Pindar, *Ol.* ii. 120.)

Elytrum (Gr. *ἐλυτρον*, *a sheath*). The superior or first pair of wings in four-winged insects are so called, when they are of a coriaceous and hardly flexible texture, and serve as a protective covering to the second pair; as in beetles.

Elzevir Editions. In Bibliography, the name of the works printed and published by the family of Elzevir (properly Elzevier), at Amsterdam, Leyden, the Hague, and Utrecht. The Elzevir editions are valued for their neatness, and for the elegant small types used. The Greek New Testament, the works of Virgil, and those of Terence, are considered their masterpieces, but the Virgil has been found incorrect in some places.

The first Elzevir edition known is Eutropius, published at Leyden by Louis Elzevir, in 1592. His eldest son, Matthew, died at Leyden, in 1640; and his second son, Giles, was a bookseller at the Hague in 1599. The first printer of the name was Isaac, eldest son of Matthew. His works date from 1617 to 1628. Matthew's third and fourth sons, Abraham and Bonaventura, were printers at Leyden from 1618 to 1626. Another brother, Jacob, was a printer at the Hague in 1626. For an account of the subsequent members of the family and of the editions issued by them, see the *Notice de la Collection d'Auteurs Latins, Français, et Italiens, imprimée de format petit in 12mo, par les Elzevirs*; Brunet's *Manuel du Libraire*, 3rd edit. 8vo. Paris 1820, vol. iv. pp. 533-537; and the *Essai Bibliographique sur les Editions des Elzevirs, précédé d'une Notice sur ses Imprimeurs célèbres*, 8vo. Didot, Paris 1822.

Emanant (Lat. *emanans*, part. of *emanare*, to flow out). The result of operating upon any quantic (*) ($x, y, z \dots$) with the symbol

$$\left(x \frac{d}{dx} + y \frac{d}{dy} + z \frac{d}{dz} + \&c. \dots \right),$$

where $x, y, z, \&c. \dots$ and $x, y, z \dots$ are cogredient facients, is called the p^{th} emanant of that quantic. Every such emanant is a covariant (usually in two sets of cogredient facients) of the original quantic. Every invariant of the emanant, formed by considering the facients $x, y, z \dots$ as constants, is a covariant of the original quantic. Thus the second emanant of any binary quantic u being

$$x^2 \frac{d^2 u}{dx^2} + 2xy \frac{d^2 u}{dx dy} + y^2 \frac{d^2 u}{dy^2},$$

we have, on considering it as a function of x', y' , the invariant

$$\frac{d^2 u}{dx'^2} \cdot \frac{d^2 u}{dy'^2} - \left(\frac{d^2 u}{dx' dy'} \right)^2,$$

which is a covariant of α , in fact its Hessian. [HESSIAN.] In geometrical applications the emanants of a quantic represent the several polar curves or surfaces of a given point. [POLARS AND POLARS.]

Emanation, System of. In Philosophy, a synonym for PANTHEISM [which see].

Emancipation (Lat. *emancipatio*, from *mancipio*, *I sell*, or deliver over the tangible property in anything). By the ancient Roman law, the son stood in the relation of a slave to the father. By a fiction of that law, the son might be freed from this relation by being three times sold (*mancipatus*) by the father. Hence the enfranchisement of the son derived from this ceremony the name of *emancipation*. In course of time, various modes of emancipation, both tacit and express, became recognised by the Roman jurisprudence. The word, in countries following that law, signifies the exemption of the son from the power of the father, either by express act, or by implication of law. By the present civil law of France, majority (and with it emancipation) is attained at twenty-one years of age; and the marriage of a minor emancipates him. (*Code Civil*, lib. 1. c. iii.) In ordinary language, emancipation is used in a general sense to signify the enfranchisement of a slave, or the admission of particular classes to the enjoyment of rights.

Emarginate (Lat. *emarginare*, *to take away the edge*). In Zoology, when the margin of a part is broken by an obtuse notch, or the segment of a circle.

Emarginula. A subgenus of Gastropodous Mollusca, dismembered from the genus *Patella* of Linnæus, and characterised by a shell of a simple conical form, but having a narrow fissure extending from the margin to near the summit.

Embalming (Lat. *balsamum*, *balm*). A process adopted by the ancient Egyptians, chiefly for the preservation of dead bodies from putrefaction. The term is derived from the use of balsamic substances in the operation; in addition to these, saline substances and tanning materials seem also to have been used. [MUMERY.]

Embankment. A raised mound of earth, for the purpose of carrying a roadway, for forming a barrier of defence against a sea or a river, or for the purposes of a pier or quay. The methods adopted for each of these purposes must, of course, differ with the materials of which they are made, and they will be regulated by the local considerations which every engineer will know how to provide for. The main conditions of embankments are that the slopes should be such as should be permanent; that the weight of the bank should not be such as to force out the foot or toe; and that there should be no tendency in the surrounding ground to displace the bank. The materials must, in fact, be placed according to their angle of repose, or that angle at which they would begin to move if abandoned to themselves.

Clay lands, for instance, are liable to slip in bank, if the materials are dressed to an angle of more than 26° , whilst gravel or hard stone may be laid at 34° . Regularly coursed stone may be laid at a much larger angle. The description of bank will also regulate the slope to some extent, for should it be required to resist the pressure of water on one side, it is found that the slope towards the water had better be 34° , and that towards the open country 26° , with a considerable thickness at the crown. The tendency of the subsoil of an embankment to compress under the effects of the load brought upon it may be resisted by widening the base, by stepping the foundations, and by filling the core or the heart of the embankment with some light and bulky materials. The best remedy for this inconvenience is, however, to isolate the foundation by a system of piling.

Great care must be taken to get rid of any water that may filter through the materials or the seating of an embankment, and the drains must be so provided that all danger of ravinement shall be avoided. If possible, the earthwork should be carried up in layers, and the earth rammed, to insure the equal compression of the materials; but executed as the railway banks are at the present day, it is hardly possible to obtain this perfection of execution. A useful precaution consists in dressing the slopes and covering them with vegetable soil, which would allow of their being turfed; this of course cannot be done when the bank is formed of gravel, or of some descriptions of stones.

The largest embankments of modern times are the Tring cutting of the North-Western Railway, which contains one million and a half yards; the Gadelbach cutting, of one million and three-quarters, on the Ulm and Augsburg Railway; and the Oberhäuser embankment, on the Augsburg and Lindau line, which contains as much as two millions and a half yards cube.

At the present day much attention has been directed to the nature of embankments, by the accidents that have occurred to the reservoirs of Holmfirth and Bradfield (Sheffield), by the failure of the enclosure of the Fenlands in the neighbourhood of King's Lynn, and also in consequence of the great operations undertaken by the Metropolitan Board of Works for the reclamation of the waste lands on the banks of the river Thames. [QUAY WALLS; RESERVOIRS; RIVER BANKS.]

Embargo (Span.). A restraint or prohibition imposed by the public authorities of a country on merchant vessels or other ships, to prevent their leaving its ports. Embargoes are usually imposed only in time of war, or in apprehension of an invasion; in which cases the government employs the ships under embargo in armaments, expeditions, and transportation of troops, &c. When it is found necessary to stop the communication of intelligence between any two places, an embargo is laid upon all ships, both foreign and under the national flag.

EMBASSY

Embassy. [AMBASSADOR.] *abellia* (the Cingalese name). A common Indian species of this genus of *Myrsinaceæ*, *E. Ribes*, yields berries, which are sold to traders for the adulteration of black pepper, which they resemble, having moreover a slight pungency. They are anthelmintic.

Ember Days. In the church calendar, certain fast days first appointed by Pope Calixtus, A.D. 220, for imploring a blessing on the fruits of the earth, and on the ordinations performed at these times. They occur four times a year, being the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the Feast of Pentecost or Whitsunday, after the festival of Holy Cross on the fourteenth of September, and after the festival of St. Lucia on the thirteenth of December. The weeks in which the ember days fall are called *ember weeks*. The term is by some connected with A.-Sax. *semyrian*, Dan. *emmer*, in the sense of *cashes*, which the primitive Christians strewed on their heads at these solemn fasts; but the forms *quatember*, Dutch *temper*, Swed. *tamperdag*, *ymber-dagar*, show the process of corruption from the Latin words *quatuor tempora*, *the four seasons*.

Emberiza. The name of a genus of Passerine birds, characterised by having the upper mandible narrower than the under one, with the edges turned inwards, and with a hard knob on the palate: the entire bill has the usual short strong conformation of the *Conirostrat* tribe of Passerine birds. It is now the type of a family, subdivided into minor genera, under the name of *Emberizidæ* or Buntings.

Embezzlement (perhaps from the obsolete verb *bezzle*, to *swallow* or *waste in riot*). In Law, a felony, consisting of the same class of acts which would in any other case amount to larceny, when committed by one employed as a clerk or servant, and by virtue of his office, on the goods and chattels of his employer.

Emblazoning. [HERALDRY.]

Emblem (Gr. *ἔμβλημα*, literally *something inserted*). This term has various significations; but it is used most frequently in English to signify a figurative representation, which by the power of association suggests to the mind some idea not expressed to the senses. In Bibliography, books consisting of a series of plates, containing emblematic subjects, with explanations, generally in verse, in Latin or modern languages, are termed *books of emblems*. They were fashionable in the latter half of the sixteenth century. The best known are the *Emblemata Alciati*, by André Alciat, a French lawyer, and the emblematic Poems of Jacob Cats.

Emblion (the native Moluccan name). One of the genera of *Euphorbiaceæ*, *E. officinalis*, formerly called *Phyllanthus Emblica*, is a moderate-sized tree grown in India and in the Archipelago, for its bark, which is used in tanning and to dye cotton black; for its fruits, which are used as a pickle, and though extremely acid are also made into sweetmeats; and for its wood, which is hard and valuable,

EMBROIDERY

and resists damp well. The plant also possesses some medical properties.

Embolismie (Gr. *ἐμβολισμός*, an *intercalation*). In Chronology, a term synonymous with *intercalary*, and applied chiefly to the additional months required to fill up the lunar cycle. [CYCLE and EPOCH.]

Embossing, Embossment (Fr. *bosse*, a *protuberance*). In Architecture and Sculpture, the raising or forming in rilievo any sort of figure, whether performed with a chisel or otherwise. It is a kind of sculpture, in which the figures rise from the plane on which they are formed; and as they are more or less prominent, they are said to be in alto, mezzo, or basso rilievo, or in high, middle, or low relief.

Embouchure (Fr.). Signifies the mouth of a river; it is used also for the mouthpiece of a musical instrument.

Embracery (Nor. Fr. *embraserie*). In Law, the offence of endeavouring to corrupt or influence a jury; punishable by fine and imprisonment.

Embrasure (Fr.). In Fortification, an opening made in the parapet of a fortified place, or breastwork of a battery, through which the guns are fired. The embrasures are usually made about two feet wide at the interior extremity or neck, and half as thick as the parapet at the exterior crest, while the sole or lower surface is at the height of about 2½ feet above the platform on which the carriage of the gun is placed; but their forms and dimensions are, of course, varied according to their position with regard to the point against which the fire is to be directed, and the kind of piece to be fired through them.

Embrocation (Gr. *ἐμβρίχμα*, *I foment*). A fluid application to any part of the body when painful or inflamed.

Embroidery (Fr. *broderie*). The name given to the art of working figures on stuffs or muslin with a needle and thread. All embroidery may be divided into two sorts, embroidery on *stuffs* and on *muslin*: the former is used chiefly in church vestments, housings, standards, articles of furniture, &c., and is executed with silk, cotton, wool, gold and silver threads, and sometimes ornamented with spangles, real or mock pearls, precious or imitation stones, &c.; the latter is employed mostly in articles of female apparel, as caps, collars, &c., and is performed only with cotton. In Germany this division is indicated by the expression *weisse* (white or muslin), and *bunte Stickeres* (coloured or cloth) embroidery. The embroidery of *stuffs* is performed on a kind of loom or frame; that of *muslin* by stretching it on a pattern already designed. The modes of embroidering stuffs or muslin with the common needle are very various; but they consist for the most part of a combination of ordinary *stitches*. The art of embroidery was well known to the ancients. Long before the Homeric age the women of Sidon had acquired celebrity for their skill in embroidery. At a later period, this art was introduced into

EMBRYO

Greece; and to such a degree of skill did the Grecian women attain in it, that their performances were said to rival the finest paintings. In our own times the art of embroidery has been cultivated with great success, more especially in Germany and France; and though for a long period it was practised only by the ladies of these countries as an elegant accomplishment, it is now regarded as a staple of traffic, and furnishes employment for a large portion of the population. A great impetus has been given to the cultivation of this art, both on the Continent and in England, by the invention of a machine which enables a female to execute the most complex patterns with 130 needles, all in motion at once, as accurately as she could formerly do with one. But as no account of this remarkable invention which we might give could be intelligible without the aid of illustrations which would be out of place in this work, we must refer the reader to Dr. Ure's *Dictionary of Arts, &c.* for full information respecting it. One such machine with 130 needles is estimated to perform daily the work of fifteen hand embroiderers employed in the ordinary way. Many of them are now mounted in Germany, France, and Switzerland; and in Manchester there is one factory where they do beautiful work. (*Art of Needlework*, edited by the countess of Wilton, London 1840.)

Embryo (Gr. *ἐμβρυον*, from *ἔμβρι*, *I bud forth*). In Botany, a fleshy body seated in the interior of the seed, and constituting the rudiment of the future plant. It is divided into three parts: a *plumule* or growing point, a *radicle* or root, and a *cotyledon* or *cotyledons*. It is the vegetable fetus; and is so tenacious of life under particular circumstances, that there are well-attested instances of its having preserved its vitality much beyond 1,000 years.

The term is also applied to the fetus in utero before the fifth month of pregnancy.

Embryotomy (Gr. *ἐμβρυοτομία*). The operation of cutting the fetus out of the womb.

Emerald (Fr. *émeraude*). A mineral occurring in green six-sided prisms, and much valued as a gem. It is a silicate of alumina and glucina. The colour is due to oxide of chromium. The most celebrated modern locality of the emerald is Muzo, in New Grenada, where it is found in a limestone containing ammonites; emeralds are also found in Peru, at Cundina-Marco in Old Columbia, Canjargum in Hindustan, and in the Henbach Valley, Salzburg. The mines from which the ancients obtained their emeralds are said to have been situated near Mount Zabarah, in Upper Egypt.

EMERALD. In Printing, a kind of type one size and a half smaller than that used in this work. [TYPE.]

Emeriti (Lat.). The name given to Roman soldiers who had fulfilled the legal term of military service.

Emergence (Lat. *emergo*, *I rise*). In Astronomy, the reappearance of the sun, moon, or planets, or of a star, from behind the celestial

EMETIC TARTAR

body by which it has been eclipsed. The phenomena of *immersions* and *emergions* are of considerable use in determining the longitudes of places.

Emery (from Cape *Emeri*, in the island of Naxos). An amorphous form of Corundum. It occurs massive, granular and compact, and is generally opaque. It consists of alumina frequently rendered impure by oxide of iron and silica. It is characterised by excessive hardness, and its powder is used in cutting and polishing glass, gems, steel, and other metals. The greater part of the emery used in this country is obtained from the island of Naxos in the Grecian Archipelago. [CORUNDUM.]

Emetics (Gr. *ἐμετικά*, *provoking sickness*). Medicines which occasion vomiting. The only vegetable emetic in general use is *ipeacacuanha*, from ten to twenty grains of which is a dose; the chief mineral emetics are the *tartrate of antimony and potash*, or *emetic tartar*, *sulphate of zinc*, and *sulphate of copper*. When it is merely wished to evacuate the contents of the stomach in cases where it is disordered by improper food, twenty grains of ipecacuanha in an ounce of water is a safe and good emetic; it generally operates in from ten to twenty minutes, and its action may be assisted by chamomile tea or warm water. At the beginning of fevers or inflammatory disorders, an emetic is often advantageously administered, and then ten or fifteen grains of ipecacuanha with half a grain or a grain of emetic tartar in an ounce and a half of water is to be preferred: the perspiration which the vomit induces should be kept up by remaining in bed, and by warm drinks or other proper remedies. Where poisons have been swallowed, the stomach is often insensible to these means, especially where large doses of opium are concerned; and then half a drachm of sulphate of zinc or of sulphate of copper may be dissolved in three ounces of warm water, and a third part of the solution taken every ten minutes till it operates. In such cases, however, the stomach-pump is principally to be relied upon. When emetics are given in small doses, they produce *nausea*, and to this extent they have proved useful in restraining hemorrhage of the stomach and lungs. Emetics should be avoided in all plethoric habits, and where there are any symptoms announcing fulness of the vessels of the head; in hernia, in the advanced stage of pregnancy, and in active inflammations. They should also be given with the utmost caution to young children; and when given, ipecacuanha should be resorted to. Old chronic pains and obstinate rheumatism are sometimes relieved by an emetic.

Emetic Tartar. A triple salt, composed of oxide of antimony, potassa, and tartaric acid. It is soluble in eighteen parts of cold and in three of boiling water. In the dose of from half a grain to two grains it operates as a powerful emetic and sudorific; in smaller doses, it acts upon the bowels, and is diaphoretic.

Emetic tartar is also a powerful local irri-

EMETINE

tant, and when applied in the form of ointment, or lotion, it produces a pustular eruption.

In excessive doses (twenty to forty grains), it acts as an acrid poison, and is liable, even in small doses, to poison young children. In cases of accidental poisoning by this salt, vomiting must be promoted by the use of warm water mixed with butter, oil, or grease, and by the administration of strong green tea, infusion of oak bark, or other forms of *tannin*, which, by decomposing the salt, act as direct antidotes, inasmuch as *tannate* of antimony seems to be nearly inert.

Emetine. A substance discovered in 1817 by Pelletier in ipecacuanha. It is white, pulverulent, and bitter; easily soluble in hot water and alcohol, and intensely emetic. It exists in ipecacuanha to the amount of about 16 per cent., and appears to be the sole cause of its emetic property.

Emigration (Lat. *emigratio*). To migrate is to move from one place to another, and the character of the migration was determined in Latin by the preposition denoting the direction taken. Hence *demigrare* is to change one's house in the same locality or city, *emigrare* is to quit the city, *immigrare* is to enter it.

The practical significance of emigration, in its modern sense, is twofold: first, by its relieving a country of its surplus population; next, by its extending and enlarging the field over which civilisation may be induced, and indirectly by its developing the characteristics of a particular race. The former of these ends is wholly economical; the latter is relative to the history of civilisation, and the political capacities and energies of some races of mankind as contrasted with others.

It is quite clear, unless some checks, natural and voluntary, are put upon population, that the increase of numbers would soon outrun the means of subsistence. Among these voluntary checks, one of the most notable is that which prompts men to seek their fortunes in some less densely occupied portion of the earth's surface. It is well known that Europe has been twice or thrice peopled by different races; and in almost every case, the migration of tribes has been prompted by the pressure which population has put upon the means of living. This compulsory emigration was symbolised in Roman history under the name of *ver sacrum*; the persons born in the year in which the vow known by this formula was taken, being constrained to emigrate when they reached adolescence. Similarly, in the ancient Greek communities, where the limits of population were rapidly reached, the practice of emigration was constant, and the process was surrounded by specified solemnities.

It does not appear that countries from which emigration proceeds rapidly, suffer, except under particular circumstances, any great decrease in their population. As long, indeed, as a country is in a state of economical progress, and therefore capital is rapidly accumulated and beneficially employed, the same area will suffice to

EMINENCE

maintain an increasing number of inhabitants, and emigration will not in general be so considerable a relief to population, as it is the resort of energetic and active individuals. At all times, any attempt to check the disposition towards emigration arises from a misconception of the province of government, and ends in increasing discontent among those whose action is hindered or prevented.

The region to which emigration proceeds most rapidly is the countries occupied by the United States. The passage is easy and comparatively short, the amount of land naturally clear is great, and the wages of labour as well as the profits of capital are generally high. How far the disposition to proceed to these parts of the world may be checked by recent events, it is not, perhaps, possible to predict; but the subjoined table will show that no great discouragement has been felt as yet.

The extension of the English race, with its language and literature, is a phenomenon of the highest interest to ourselves. The time cannot be far distant when our language will be spoken over the largest part of the civilised world, and our race occupy the most temperate regions of the globe. It bids fair to settle the greater part of the North American continent, and to colonise the largest and most fertile islands in Australasia.

Emigration to the British colonies is considerably aided by a practice suggested in the first instance by Mr. Gibbon Wakefield, of devoting the produce of public land sales to the fund for assisting emigrants.

The following table shows the number and destination of the emigrants who have left the United Kingdom from 1839 to 1864 inclusive:—

Years	North American Colonies	United States	Australian Colonies and New Zealand	All other Places	Total
1839	12,658	33,536	15,786	227	62,207
1840	32,293	40,642	15,850	1,568	90,743
1841	35,164	45,017	32,525	2,768	115,482
1842	36,123	32,852	8,594	1,885	128,514
1843	23,518	28,335	8,476	1,681	67,212
1844	32,924	43,660	2,229	1,673	70,686
1845	31,603	58,538	830	2,330	93,501
1846	45,489	82,289	2,347	1,626	129,851
1847	109,680	142,164	4,949	1,467	258,270
1848	31,005	188,233	22,944	4,897	346,989
1849	41,367	219,440	32,191	6,490	399,488
1850	32,961	225,078	16,037	8,773	382,849
1851	42,605	267,357	21,532	4,472	335,966
1852	32,673	244,261	67,881	3,749	348,764
1853	34,432	230,585	67,881	3,129	335,927
1854	43,761	199,065	82,237	9,368	323,429
1855	17,966	103,414	52,309	5,118	176,807
1856	16,378	111,837	44,584	8,755	176,554
1857	21,001	126,905	61,248	9,721	218,875
1858	9,704	69,718	39,295	6,367	118,072
1859	6,689	70,303	31,013	12,427	120,432
1860	9,786	67,500	24,302	6,881	128,469
1861	12,707	49,784	22,738	6,561	91,770
1862	15,522	58,706	41,843	6,143	121,214
1863	18,083	146,813	53,054	6,808	223,758
1864	12,721	147,042	40,842	6,195	206,900

Eminence (Lat. *eminentia*). A title of honour borne in Europe by various dignitaries at different times; but appropriated to cardinals by a papal decree of the year 1630.

EMINENTIA COLLATERALIS

Eminentia Collateralis (Lat.). This name has been given by Anthropotomists to the prominence which extends transversely across the spot where the *hippocampi major and minor* unite in the lateral ventricle of the human brain. It has also been termed *eminentia lateralis s. Meckelii*.

Emir (Arab. *chief or lord*). The khalifs took the title of *Emir-al-Mumenin*—chief or commander of the faithful. The title is now given by prescriptive usage to those who are considered to descend from Mohammed, by his son-in-law Ali and his daughter Fatima. [SCARBIF.] But when joined to another word expressive of a particular command or office, it is a common title of dignity; as *Emir-al-Omrah*—a title given by the Turks to viziers and pachas, &c. [MIRZA.]

Emmenagogue (Gr. *ἐμμησίου*, *monthly*, and *ἀγω*, *I move*). Medicines which promote the menstrual evacuation.

Emollients (Lat. *emollio*, *I soften*). Medicines which are supposed to relax the living animal fibre, and are directly opposed to *tonics*.

Empalement (Lat. *in*, and *palus*, *a stake*). A cruel punishment, which consisted in thrusting a stake into the body of the victim, and then leaving him to perish. It was frequently practised by the ancient Romans, and more recently by the Turks and other barbarous nations.

Emperor (Lat. *imperator*). The title *imperator* was conferred by the Romans on their consuls, in their military capacity, after this authority had been confirmed to them by the *comitia curiata*. On the fall of the republic, it was conferred, first for a definite period and afterwards for life, on Augustus. The authority of the Roman emperors was formed principally by the combination of the chief offices of the old republic in a single person; besides which, some extraordinary powers were conferred. Thus, Octavius held the titles of *imperator*, *proconsul*, *tribune*, and *pontifex maximus* or high priest; and was invested with perpetual consular authority, and also with that of the censorship. Besides this, he was termed *princeps of the senate*, and *Augustus*, which designation descended to his successors; but he was much more moderate in his use of titular dignities than his successors, contenting himself with substantial power. The provinces of the empire were divided between the senate and emperor, who appointed their governors, distinguished by the respective titles of *proconsul* and *propraetor*; but this division threw all the armies into the hands of the latter, as he took for his share the frontier provinces. The emperors appointed their own successors, who were dignified with the title of *Cæsar*, and in later times enjoyed a share in the government. Diocletian first divided the care of the empire with a second Augustus in the person of Maximian, and each of these colleagues associated with himself a Cæsar. After the court was removed to Constantinople, the old titles and forms of the republic vanished by degrees, and

EMPIRIC

the emperors assumed the style of Oriental princes. [CÆSAR.]

The title of emperor of the Romans, with that of Augustus, was conferred in 800 by Pope Leo III. on Charlemagne, by whose successors it was held until the dissolution of the Holy Roman Empire in 1806. The imperial style has since been assumed by the archdukes of Austria, by the Bonapartes in France, and by the czars of Russia.

Empetraceæ (*Empetrum*, one of the genera). A small order of monochlamydeous Exogens, of the Euphorbial alliance. They are diclinous heath-like plants, with small axillary flowers and fleshy fruit. The fruit of *Empetrum nigrum*, the Black Crowberry, is sometimes eaten, and a fermented liquor is also prepared from it.

Emphasis (Gr. *ἐμφασις*). In Elocution, the stress laid on particular words or syllables in a sentence, in order to express or enforce a meaning.

EMPHASIS. IN MUSIC. [ACCENT.]

Emphysema (Gr. *ἐμφύσημα*, *an inflation*). A diseased condition of lung generally consequent on chronic bronchitis, consisting in dilatation of the air-cells and occasional rupture of two or more into one. Another and rarer form is caused by escape of air from the lung by rupture, when air-bubbles are found under the pleura or covering membrane of the lung.

Emphyteusis (Gr. *ἐμφυτεύσις*, *I plant*). In the Civil Law, a contract by which houses or lands are given to be possessed for ever, or for a long term, and an annual rent or pension (*canon emphyteuticus*), either in money, grain, or any other thing, reserved and made payable to the grantor as a recognition of his paramount title. The grantor is said to retain the *dominium directum*, the grantee to acquire the *dominium utile* or *usufruct*. The Scottish *rent in feu-farm* resembles the emphyteusis. From this word (pronounced in the lower age of Latinity, *emphytefsis*) it is supposed that *feif* (*fevodum*, *feodum*) is derived.

Empire (Lat. *imperium*, the power conferred by the state on those who were appointed to command the army). The dominions under the sway of the Roman emperors were the first to which the term *empire* was applied: they consisted of two grand divisions, the Empire of the East, or, as it was afterwards called, the Lower Empire; and the Empire of the West. The latter became, about the end of the ninth century, the Holy Roman Empire. (Bryce, *Holy Roman Empire*.) But the term *empire* has in several instances been employed to designate a large extent of dominion, without reference to the title of the ruler or sovereignty of a country: thus we hear of the empire of Persia, Hindustan, &c. The dominions of the queen of England are invariably designated the British Empire; and the epithet *imperial* is officially prefixed to the parliament of the United Kingdom.

Empiric (Gr. *ἐμπειρικός*). One whose knowledge is founded on experience. The empiric school of medicine was opposed to the

EMPLASTICS

dogmatic; it appears to have originated with Serapion of Alexandria. The empirics considered the foundation of medical science to rest upon experience, derived either directly from experiment or from chance and imitation. They were, however, a pretentious and generally ignorant sect; so that the term *empiric* is generally applied to quacks and pretenders, without reference to its strict etymology, which should have limited it to the study of medicine, in accordance with the principles of Lord Bacon's philosophy.

Emplastics (Gr. *ἐμπλαστικός*, *clogging*). Medicines which have a tendency to cause constipation and shut up the pores of the body.

Emporium (Gr. *ἐμπορίον*). A city or place where great commercial transactions are made. The word has been in use in England for more than three centuries.

Emprosthenos (Gr.). A spasmodic action of the muscles, by which the body is involuntarily drawn forwards. [*ISTANUS*.]

Empyema (Gr. *ἐμπύημα*, *suppuration*). A collection of purulent matter in the cavity of the thorax. This is an occasional termination of pleurisy, and is attended by difficulty of breathing and inability to lie on the side opposite that which is affected; an external swelling is sometimes perceptible, and the matter has occasionally been let out by making an opening between the sixth and seventh ribs.

Empyreol Air. Oxygen gas.

Empyreuma (Gr. *ἐμπύρευμα*, from *ἐμψυεῖν*, *I kindle*). A burnt odour. Hence the oils obtained by distilling various organic substances at high temperatures are called *empyreumatic oils*.

Emu. A three-toed Struthious bird, peculiar to Australia, differing from the rheas of South America in the extreme shortness of its wings, and from the cassowary of Java in the absence of the horny projection on the head.

Emulgent (Lat. *emulgeo*, *I milk out*). The artery and vein which go from the aorta and vena cava of the kidney are so called, from the ancient notion of the blood being, as it were, strained in the kidneys.

Emulsion. [*SNAPTAE*.]

Emulsion (Lat. *emulgeo*, *I milk*). A milky liquid; as *almond emulsion*.

Emunctories (Lat. *emunctorius*). The excretory ducts of the body.

Emydines, **Emydina**. A section of Chelonian reptiles or tortoises, having the genus *Emys* as the type.

Emydo-saurians, **Emydo-sauria** (Gr. *ἐμύς*, *a water-tortoise*, and *σαῦρος*, *a lizard*). The name of an order of the class *Reptilia*, including the tribe of Crocodiles (*Crocodyliens*, Cuv.), which form part of the order *Sauria* of the *Edgés Animal*.

Emeliosauria (Gr. *ἐμελίος*, *of the sea*, and *σαῦρος*, *a lizard*). A name applied to the entire group of extinct Saurians, in the organisation of which paddles, like those of the whale or turtle, were combined with the head and trunk of a crocodile. [*ΙΣΤΗΥΟΣΑΥΡΟΣ*; *ΠΛΗΜΜΑΤΡΟΣ*; *ΣΑΥΡΟΡΕΥΤΗΡΙΑ*; and *ΙΣΤΗΥΟΡΕΜΜΥΙΑ*.]

ENAMEL PAINTING

(Fr. *émail*). A semitransparent or opaque glass. Common glass fused with oxide of tin is converted into common white enamel. Various coloured enamels are used in porcelain and enamel painting. [*PORTRAIT*.] The term *enamel* is also applied to the hard external covering of the teeth: it differs from the bony part of the tooth, or *dentine*, in containing less organic matter, the hardening principle being almost pure phosphate of lime. [*TEETH*.]

Enamel Painting (Fr. *en émail* or *esmail*, Lat. *esmalum* or *smaltum*, Ital. *smalto*). In Painting, the art of applying vitrifiable colours on thin plates of metal (gold or copper) which are melted on to them, or on pottery, or even glass itself: the glass painting of the present time is chiefly enamelled. This art was practised by the ancient Egyptians and Etruscans. It was very commonly applied to ecclesiastical utensils and furniture during the middle ages, and was much in vogue with the Byzantine Greeks and with the Moors. The town of Limoges, in France, acquired especial celebrity for this class of art, on metal plates. During the Revival in Italy, especially in the Cinquecento period, it was much employed for table services of pottery and for the vessels of apothecaries. The famed Faenza or Majolica ware, of which so much is now preserved at the South Kensington Museum, is simply enamelled earthenware. The museum possesses also some fine examples of the *émaux de Limoges*, which are remarkable for the uniformity of their grey colouring. One of the first good enamellists, especially of portraits, was John Petitot of Geneva (1607-91). The various colours used are prepared from oxides of different metals, melted with some vitrescent mixture or *flux*, and laid on with a fine brush, the medium being oil of spike, or turpentine, or some other essential oil; and it is easy to conceive, says Mr. Aikin, 'how much the difficulties of this nice art are increased where the object is not merely to lay a uniform coloured glazing on a metallic surface, but also to paint that surface with figures and other designs that require extreme delicacy of outline, accuracy of shadowing, and selection of colouring. The enamel painter has to work, not with actual colours, but with mixtures which he knows from experience will produce certain colours after the operation of the fire.' This work requires several firings. The outline is first burnt in, after which the parts are filled up gradually with repeated burnings to the last finishing touches.

The principal colours are oxides of lead, platinum, uranium and chromium: different colours require different treatment. Silica, borax, and red oxide of lead form a *flux* for some colours: the oxides of iron and manganese are not approved of. The enamel is made opaque and white by oxides of tin or antimony. See the *Edinburgh Philosophical Magazine* for June 1837, which contains a notice of enamel painting by Mr. Alfred Essex; and De Laborde's *Notice des Émaux du Louvre, Histoire*, Paris 1852.

ENARTHIROSIS

Enarthrosis (Gr. *ἐνάρθρωσις*, from *ἐν*, *in*, and *ἄρθρον*, *a joint*). The ball-and-socket joint.

Encampment. In Military affairs, the position occupied by an army, or body of troops, having pitched tents or erected huts for temporary lodgings. [CAMP.]

Encaustic (Gr. *ἐγκαυστικός*, from *καῖναι*, *the angle of the eye*). A small tumour or excrescence growing from the inner angle of the eye.

Encarpus (Gr. *ἐγκαρπός*, *containing fruit*). In Architecture, the festoons on a frieze, consisting of fruits, flowers, leaves, &c.

Encaustic (Gr. *ἐγκαυστική*, from *καῖναι*, *a burning*). A common method of painting, and the most durable of those employed by the Greeks, so called from the process of burning the picture in when completed. It was not developed until the later or more perfect period of Greek art. The pictures were executed with wax colours (*ceræ*), and the whole was afterwards burnt in with a hot iron; the painter himself signing his work with the word *ἐνέκαυσεν* (*burnt it in*), as *Nicias ἐνέκαυσεν*. These pictures were executed with the cestrum [CESTRUM] and with the pencil: the colours though mixed with wax could be laid on with water. The effect of an encaustic picture cannot have been very different from the ordinary *tempera* or water-colour picture, as the men who practised either were equally celebrated; and Pausanias, an encaustic painter, undertook to repair the pictures of Polygnotus at Thebes, which were in *tempera*. Both water-colour and *tempera* pictures were polished with a wax or encaustic varnish. The same method was applied to the colouring and varnishing of statues. [POLYCHROMY.] A common method of encaustic was used for colouring ships; the colours were laid on with a brush, hot; but this scarcely comes under the category of fine art. If the colours were not laid on with water on the finer pictures, the cestrum apparently served the purpose quite as well. The finer blending of tints being effected by the cauterium or hot iron, some resin was necessarily mixed with the colours to enable them to harden after the process of burning in. (Wornum, *Epochs of Painting*, 1859.)

Encinte (Fr.) or **Body of the Place**. In Fortification, the line of works which forms the main enclosure of a fortress.

Encephalocoele (Gr. *ἐνέφαλος*, *the brain*, and *κήλη*, *a tumour*). Hernia of the brain. There are two kinds of this disease: one occurs in young infants, before the skull is completely ossified; the other presents itself after the destruction of a part of the skull in consequence of disease, accident, or the operation of the trepan.

Encephalon (Gr. *ἐνέφαλος*, *within the head*). The brain. The contents of the cranium.

Enchantment (Fr. *enchantement*; Lat. *incantamentum*, from *incantare*, *to sing*). The name given to the charms or ceremonies to which magicians have recourse in the practice of their art. [MAGIC; DEMONOLOGY.]

ENDLESS SCREW

Enchasing. [CHASING.]

Enchiridium (Gr. *ἐνχειρίδιον*, from *ἐν*, *in*, and *χείρ*, *the hand*). In Literature, a brief and useful compilation; a *manual*. The ethical treatise of Epictetus is termed his *Enchiridium*.

Enclave (Fr.). In Heraldry, anything let into another, especially when the piece so let in is square.

Enclitics. [PARTICLES.]

Enkratites (Gr. *ἐγκρατής*, *temperate*). In Ecclesiastical History, a Gnostic sect who condemned marriage. (Eusebius, *Hist. Eccl.* iv. 29.)

Enocrinital Limestone. The name given occasionally by geological writers to the carboniferous limestone of the upper Paleozoic period, parts of which are so loaded with the fragments of encrinites that the whole mass seems made up of those fossils.

Encrinites. [CRINOIDEANS.]

Encumbered Estates Act. [INCUMBERED ESTATES ACT.]

Encyclopædia. [CYCLOPÆDIA; DICTIONARY.]

Encyclopædists (Fr. *encylopédistes*). A name given to the French writers of the last century, whose works and influence, by stimulating freedom of enquiry and discussion, prepared the way for the Revolution.

Encystation (Gr. *ἐν*, and *κύστις*, *a bag*). The process undergone by certain Infusoria previous to fission. They coat themselves with a secretion of gelatinous matter, which gradually hardens and encloses the body in a *cyst*. Sometimes peculiar vesicular bodies become formed in the interior of such cysts, through which they finally burst, and becoming ruptured at the apex, give exit to the embryos contained in their interior.

Encysted. A term applied to tumours which are enclosed in a sac or cyst.

Endecagon or Undecagon. [HENDECAGON.]

Endellionite. A name given to the triple sulphuret of antimony, lead, and copper found in the mine Hud Boys, in the parish of Endellion, Cornwall. [BOURNONITE.]

Endemic (Gr. *ἐνδημος*, *among the people*). A disease peculiar to a certain class of persons, or to a certain district. Thus, agues or intermittent fevers are endemic in low countries, the *goutte* in the Alps and parts of Derbyshire, the *plaga Polonica* in Poland. [EPIDEMIC.]

Endermic Method. The application of medicinal agents to the denuded dermis. A blister is first usually applied: when the cuticle is elevated, an opening is made in it to allow the serum to escape, and the medicine is then applied to the dermis, either with or without removing the cuticle. Morphia, strychnia, and various other agents have been thus applied.

Endive. An annual or biennial herbaceous composite plant, used in salads, the *Cichorium Endivia* of botanists.

Endless Screw. A piece of mechanism formed by combining the screw with a cog-wheel, or by making a screw act on the threads of a female screw sunk in the edge of the

ENDOCARP

wheel. The axis of the screw may be either in the plane of the wheel, or at right angles to it; in the latter case it is called the *American endless screw*. In its mechanical principle the endless screw is a combination of the inclined plane and the lever.

Endocarp (Gr. *ἔνδον*, *within*, and *καρπός*, *fruit*). The inner coat or shell of a fruit, as the stone of a Cherry.

Endochrome (Gr. *ἔνδον*, and *χρῶμα*, *colour*). The colouring matter of plants.

Endogens (Gr. *ἔνδον*, and *γίνομαι*, *One* of the primary classes of plants, so called because their stems grow by successive additions to the inside; that is to say, by the addition of woody vessels towards the interior, so that the outer part is the oldest and hardest. They have no woody rings as in Exogens, and no true medullary rays. They are usually known by the veins of their leaves running parallel with each other, without branching or dividing. Grasses, Lilies, the Asparagus, and similar plants belong to this class, which in warm countries contains trees of large size, such as Palms and Screw Pines.

Endophyllous (Gr. *ἔνδον*, and *φύλλον*, *a leaf*). The young leaves of Monocotyledons, from their being evolved within a sheath, while those of Exogens are not so enclosed.

Endopleura (Gr. *ἔνδον*, and *πλευρά*, *the ribs or side*). In Botany, the internal integument of a seed.

Endorhizæ (Gr. *ἔνδον*, and *ρίζα*, *a root*). A term invented by Richard for the embryo of Monocotyledons, in which the radicle has to rupture the integument at the base of a seed prior to entering into the earth, appearing as if it came from within the mother root.

Endorse (from Lat. *in*, and *dorsum*, *the back*). In Heraldry, the smallest diminutive of the pale.

Endorsement. [EXCHANGE.]

Endosiphonites (Gr. *ἔνδον*, *internal*; *σίφων*, *a tube*). A genus of extinct Cephalopods, with chambered convolute discoidal shells, having the siphon placed at the inner side of the turns, as in the Spirula. The *Endosiphonites* characterise the slate rocks of the Cambrian system, and have not yet been observed in the Silurian formation.

Endosmometer (from endosmose, and Gr. *μέτρον*, *measure*). In Physiology, an instrument invented by M. Dutrochet, to measure or demonstrate the rapidity with which one or other of two mixing fluids, of different densities, will pass into each other: and by which the less dense fluids are shown to pass with greater rapidity into the more dense fluids, than vice versa: in other words, that *endosmosis* is more rapid than *exosmosis*. A simple form of the instrument is a graduated tube, expanded into a bell at one end, over which a portion of membrane may be tied. If the bell be filled with a fluid of much density, such as a strong solution of salt, and be immersed in one of less density, as water, the water will endosmose, or pass into the solution, more rapidly than the

ENFRANCHISEMENT

solution will exosmose or pass out. But if the water were put into the bell and the saline solution outside, the directions of the currents would be reversed. In both cases, however, the currents would continue until the two fluids were equally mixed on both sides of the membrane.

Endosmose (Gr. *ἔνδον*, and *ὥμος*, *a thrusting*). The transmission of gaseous bodies, or vapours, or liquids, through membranes or porous substances from without inwards.

Endosperm (Gr. *ἔνδον*, and *σπέρμα*, *seed*). The albumen of seeds.

Endostome (Gr. *ἔνδον*, and *στόμα*, *the mouth*). The passage through the inner integument of a seed immediately below the part called the foramen.

Endothecium (Gr. *ἔνδον*, and *θήκη*, *a cell*). The fibrous cellular tissue lining an anther.

Endowments. [FOUNDATION.]

Endymion (Gr. *Ἐνδυμίων*). In Greek Mythology, a youth loved by Selênê, who plunged him into an everlasting sleep. The local legends of Elis made him a son of Æthlios and Calycê; other legends spoke of him as a son of Zeus and Protogeneia. These names explain themselves. The word Endymion expresses the plunge of the setting sun into the sea: he is spoken of as the son of Æthlios, the struggling one, because the sun was held to toil all day, like Hercules, for the benefit of man; while Protogeneia, his mother, is the early dawn. So, again, he is made to sleep in the cave of Latmos, or forgetfulness, as Phebus is the child of Leto, the dark and veiling night.

Eneid. [ÆNEID.]

Enema (Gr. *an injection*). A medicine injected into the rectum. A clyster.

Enfocment. [FROFFMENT.]

Enfield Rifle. The arm with which all infantry in the British service are armed. It is named after the government factory at Enfield where it is made. There are two patterns: that of 1853—weight of rifle with bayonet 9 lbs. 12 oz., length 71·5 inches, length of barrel 39 inches, diameter of bore ·577 inch, three rifled progressive grooves spiral 1 turn in 78 inches; that of 1860—weight with bayonet 10 lbs. 4 oz., length of barrel 33 inches, 5 grooves. [SMALL ARMS; SMALL ARM AMMUNITION.]

Enfilade (Fr.). When a battery is placed at right angles to a line of troops or works, the shot from its guns taking that line, the fire is then called *enfilade*, the guns being fired with full charges. A trench or parapet is said to be *enfiladed* when guns are so placed that the shot can be fired into it in a direction parallel to its length.

Enfranchisement (Fr. *franchise*, *freedom or right*). In Law, the act of incorporating a person into any society or body politic; as where one is made a citizen or free burgess of a town corporate. In feudal usage, a villein was said to be enfranchised when he was made free by his lord; and hence is derived the popular signification of the term. For enfranchisement of land, see COPYHOLD.

ENGAGED COLUMNS

Engaged Columns. In Architecture, columns attached to walls by which a portion of them is concealed; they never stand out less than one-half from the wall.

Engagement (Fr.). As a Military term, signifies a battle either by sea or land; but it is applied more frequently to the former, being synonymous with *action*. An engagement between two ships is called, simply an *action*: between fleets, a *general action*. The conquered vessel strikes (haws down) her colours, which are afterwards replaced by those of the enemy, hoisted over them. [BATTLE.]

Engine (from the Latin *ingenium*, used, like the Greek *μηχανή*, in the sense of a machine). In Mechanics, this term is used to denote generally any kind of machine in which two or more of the simple mechanical powers are combined together.

Engineering (from the Latin *ingenium*, used in the sense of an engine, like Aus, in Artillery, which see). Strictly, the art of managing engines; but latterly applied in a more extended sense, not only to that art, but to all manufacturing and building operations in which engines are used. It is divided into two branches, Military and Civil.

Military engineering, as a science, implies a knowledge of the construction and maintenance of fortifications, and all buildings necessary in military posts; and includes a thorough instruction on every point relative to the attack and defence of places. The science also embraces the surveying of a country for the various operations of war, and consequently an acquaintance with mathematics and facility in drawing. When at a siege the engineer has surveyed a place, he reports to the commander the weakest places, and those in which approaches may be made with most success. He draws the approaches, marks out the trenches, places of arms, batteries, and lodgements; and in general directs the workmen in these operations. He should possess a practical and theoretical knowledge of gunnery. In regard to the marine branch of military engineering, it requires of course a general acquaintance with the construction of vessels, jetties, moles, and other buildings, of that description.

Civil engineering, as its name imports, does not include the branches above named, which specially belong to the art of war; but rather relates to the formation of roads and bridges, railroads, the construction of machinery to all purposes, the formation of canals, aqueducts, harbours, drainage of a country, &c. Till the year 1780 civil engineering was little cultivated in England or on the Continent as a distinct pursuit. At that period manufacturing began to be extended by the enterprise and capital of persons eminent for their deep knowledge and persevering industry. Internal navigation was a result of this extension; communication between harbours and warehouses, as well as facility of transport from factory to factory, became absolutely necessary; hence a system of canal navigation, which will

ENGINEERING GEOLOGY

perhaps not be entirely superseded by the modern railroad. Before this time, a few jetties and piers of defence were thrown out in our seaports; but these were deteriorated sadly from the old Roman models. These ports have since become harbours of refuge, and some of them are capable of containing large navies. The introduction of the system of the ports et chaussées into France about this time also gave a great impulsion to the studies of the civil engineer; and the bridges of Huppeau, Perronet, De Cessart and Smeaton may be considered to mark an epoch in the art. The application of the steam engine to almost every purpose, independently of its importance in manufactures, has smoothed the difficulties formerly experienced in executing great works; and the numerous classes of new materials lately introduced have considerably extended the limits of the engineering profession. The substitution of the locomotive for horse traction, and the countless modifications of the wonderful power thus placed within the reach of engineers, have so materially changed the whole face of the science, that at the present day it would be necessary to write treatises on every branch of natural philosophy if it were desired to give a complete sketch of the duties of the civil engineer. The civil engineer cannot design any works for the water supply, the drainage, or the lighting of a town, without being acquainted with the principles, at least, of the chemistry of materials, the action and reaction of the water, the philosophy of light, and the nature of the materials employed by him to produce the effect. So also the mining engineer is bound to study the laws of the metals on which he works; whilst the mechanical engineer must be practically acquainted with the properties of the materials which he is employed to convert, the powers of motion, and the capabilities of producing it. The civil engineer, properly speaking, should bring to his pursuit a mind stored with every branch of applied sciences that can be enlisted in his profession.

Engineering Geology. The branch of applied geology relating to the consideration of the earth and of the various rocks at its surface, as the basis of engineering operations. Thus, earthworks, tunnels, embankments, cuttings, the artificial drainage of large tracts by operations dependent on the subsoil and the rock, water supply to large towns, and the selections of sites for various purposes, all depend on geological considerations, and not unfrequently these are of vital importance to the well-being of mankind.

The geological considerations that affect questions of this kind are chiefly mechanical and structural; as, for instance, a knowledge of the laws that govern the deposit of rocks in water, as stratified mud and sand; the laws of metamorphism, by which mud and sand are converted into limestone, sandstone, or clay, and so further into marble, quartzite, and slate; the laws according to which rocks have been dried,

fractured, upheaved, faulted, and brought into their present position; and lastly the sequence of rocks, as determined in the country where the operations are to be carried on and the knowledge exercised.

In ordinary engineering operations, as for railways, canals, or roads, the stability of earth-works may depend on the underlying rock. It is possible that by an alteration in the natural drainage, produced by a deep cutting, ground before quite permanent may become shifting, for by the trickling of water through a bed of sand or marl once cut through, not only is the support removed, but a sliding surface is prepared. Everything in such cases depends on the dip of the beds. If that is such as to render it probable that mischief would ensue, the injury when foreseen may be prevented; otherwise there is little to be done.

In tunnels, a knowledge of the stratification is essentially necessary, as without it no trustworthy estimate can be formed. By enabling the engineer to know what is the probable rock at a certain depth, and whether water is likely to come out when that depth is reached, and if so under what pressure, geology lays him under deep obligations.

Drainage of land on a large scale, required only under certain geological contingencies, is greatly assisted and rendered more economical by a due application of geological knowledge. The fact that certain rocks allow water to pass freely through them, while others stop its passage entirely, is not less important in reference to those rocks that are far away out of sight, than those at the surface. Thus calculations not referring to geological inferences will have small value and may lead to serious error. So, with regard to the places selected for storing water for large towns, the applicability of these depends on the underlying rocks, quite as much as on the rocks at the surface. The latter may be permeable without seeming so; they may be connected with permeable rocks in such a way as to injure the quality of water stored in them; and lastly there may be limits to their retentive powers, only known by reference to surrounding geological conditions.

In military as in civil engineering, a knowledge of geology is desirable. Thus in the selection of a place for encampment, not only the presence of water, but freedom from fever ought to be a matter for consideration. Many important suggestions are offered at once in reference to these matters by a consideration of the geological phenomena.

Lastly, to emigrants, and especially to those whose position involves the responsibility of selecting a place for a permanent settlement, the state of the subsoil and underlying rocks, and the conditions of water supply, are much more important than has often been suspected.

Engineers, Royal. The corps intrusted with the construction of and the keeping up of fortifications, and all military works and buildings. [ENGINEERING.] Before the peace of 1763 the duties of engineers were performed by officers

taken from the army generally; about this time the engineers were made into a permanent corps, and in 1772 the first company of sappers and miners was formed at Gibraltar. In 1783, the engineers were raised to be a royal corps, and in 1812 the sappers and miners were organised into a body of well-trained men. Until 1857 the non-commissioned officers and men were called *sappers and miners*, but this designation was then abolished, and they became royal engineers. The corps, which consists of over 5,000 men, is divided into forty companies, four of which are employed on the Ordnance Survey, six are at Chatham, and the remainder on works at home and abroad. Only men skilled in particular trades are enlisted for this corps.

England, Church of. The period at which Christianity was first preached in this country has not been settled with any certainty; but there was certainly a British church existing in the island at the time of the mission of Augustine, in the year 597, to convert the Saxons. The British church, however, at that time had shared the fate of the general British population, and had been pent up by the pressure of the heathen invaders within narrow limits at the extremities of the island. It can hardly be thought to have retained sufficient vigour to have effected the conversion of the barbarians. If such be the case, we must allow that Christianity in Britain owes at least its second foundation to the Romish see; but possibly the influence of the more primitive religion of the Britons may have had its effect in rendering the submission of the Anglo-Saxons to that see only partial. Certain it is, as has been shown from existing homilies, that some of the principal novelties of the Romanists were unknown to or repudiated by the English church, at least up to the time of Edward the Confessor. The intercourse with France, which began to take place in that reign, and the superstitious temper of the monarch, prepared the way for the introduction of the Romish power, which was furthered by the necessities of the usurpers William and Stephen. Under Henry II. royalty took the alarm, and a fierce struggle took place, in which the papal authority was eventually victorious. Under John, the triumph of Romanism was completed, when the crown of England was actually given into the hands of Innocent III. But at that very time the seeds of the Reformation were being sown among the lowest classes: sects of strolling fanatics were constantly appearing and passing away, misguided themselves, but drawing the attention of the people to the errors of the church; and at length, under the impulse given by the learning of Wiclif, taking a definite and lasting shape under the name of the Lollards. A general reformation in opinion was almost at hand, when Henry VIII. threw off the supremacy of the pope. But while he encouraged the Reformers by that step, he checked them by severe enactments upon points of belief; and, as far as he is concerned, it may be doubted whether he at all assisted the development of

the Reformation. The church of England was first reformed by law on the accession of Edward VI.; but many points of doctrine and discipline were left untouched; and the enactments of Elizabeth, by which its whole constitution was finally settled, followed rather than preceded the expressed convictions of the nation. (For the variations that have since taken place in the services of the church, see COMMON PRAYER.) The government of the church of England is episcopal, and the bishops sit in the House of Lords by virtue of the temporal baronies into which their benefices were converted by William the Conqueror. This constitution was subverted on the success of the Great Rebellion, and presbyterianism established in its stead; but the episcopal form was restored in 1660 with the return of Charles II., when the Liturgy of the church of England was legalised by statute. [UNIFORMITY, ACT OF.]

The church of England is established in Ireland, or rather the churches of the two countries are one in doctrine and discipline; and in some of the old North American colonies (especially Virginia) it enjoyed rights and dignity. But with the independence of those colonies, the church of England ceased to exist there; and the episcopal church of America, affiliated with but independent of the English communion, began its existence. The episcopal church of Scotland, again, though in doctrine and discipline nearly resembling that of England, is distinct from it. But with the extension of British colonisation, the local extent of the church of England has of late years greatly increased; there are now forty colonial bishops, and some steps have been lately taken towards the establishment of missionary bishops without any British or colonial diocese.

English. In Printing, the name of a type five lines larger than that used in this work. A type twice the size of this is called *two-line English*. [TYPE.]

English Architecture. [ARCHITECTURE, ENGLISH.]

Engrailed. In Heraldry, any object edged with small semicircles, the points turned outwards.

Engrainment. The ring of dots round the edge of a medal.

Engraving (Sax. *grafan*, to dig, as Gr. *γράφειν*, to write or paint, meant originally to scratch or scrape). The art of producing by incision or corrosion designs upon blocks of wood, plates of metal, or other materials, from which impressions or prints upon paper or other soft substances are obtained by pressure. Engraving, as an art, seems to have nearly the same relation to design and painting as typography bears to written language; and its utility and great importance must be obvious to everyone, from its capability of giving a boundless circulation to representations of the most valuable examples of the arts and of objects connected with science. By some authors it is placed among the representations called *monochromes* (*μονοχρόματα*).

Xylography, or wood-engraving, was the earliest method practised; but its origin is involved in obscurity. If we might rely on Du Halde (*Description, &c. de l'Empire de la Chine*, 4to. 1736), it may possibly have been known in China 1,120 years before Christ; though we think its invention is of a much later period, as the Chinese were not acquainted with the art of making paper till 96 a.c. It has been stated that this art was introduced into Europe from China, through the intercourse of the Venetian merchants with its inhabitants; for it is proved that engraving on wood had been practised in that part of Italy which borders on the Adriatic as early as the thirteenth century. The first wood engravings in Europe of which anything is known with certainty were executed in 1285, by a brother and sister of a noble family of the name of Cunio. They represent the actions of Alexander; and though doubts of their authenticity are expressed by Heineken, Mr. William Young Ottley, the author of the *History of Engraving*, thinks otherwise. But for the accidental discovery by Temanza, a Venetian architect, of a decree of the magistracy of Venice, in 1441, we might have been without positive proof of the practice of the art in Italy previous to 1467. This decree, dated October 11, 1441, states in substance that the art and mystery of making cards and printed figures had fallen to decay, owing to their extensive importation; and in order that encouragement might be given to native artists rather than to foreigners, it was ordered that no work of the said art, printed and painted on cloth or paper—viz. altar-pieces or images and playing cards, and whatever other work of the said art is done with a brush and printed—should be allowed to be brought into the city; on pain of forfeiting the works, besides a pecuniary penalty. This decree plainly indicates that wood-engraving had been practised in Venice some years before that date. In Germany and the Low Countries, block books seem to have existed as early as 1420, and to have given Gutenberg the hint for using movable types. At Rome, in 1467, a work entitled *Meditationes Johannis de Turrescremata*, issued from the press of Ulric Han, embellished with wood engravings, in which the design and execution of an Italian artist are evident. The decorations of the work of Valturius by Matteo Pasti, of Verona, published five years afterwards, exhibit considerable spirit and accuracy; and before the end of the fifteenth century the art had been carried to great perfection, as may be proved by the delicacy and purity with which the designs are engraved in the celebrated work of Francesco Colonna, entitled *Poliphili Hypnerotomachia*, and published in folio by Aldus. This book, now extremely rare, is full of plates, some of great beauty, from wood blocks. At this period, however, the discovery of copper-plate engraving had been made, and to this the more ancient art gave place. Maso Finiguerra, a goldsmith and sculptor of Florence and pupil of Masaccio, about the middle of the fifteenth century, seems

from the most authentic accounts to have been the person to whom the world is indebted for the discovery. In his time, and for a considerable period previously, it was the practice to decorate church and other plate with works in *niello*, which were designs hatched with a steel point upon gold or silver, then engraved with the burin, and run in, while hot, with a composition called *niello*—a compound of silver, lead, copper, sulphur, and borax, which was more easily fusible than silver, and of a black colour. In order to preserve copies of their designs, the artists were in the habit before filling the design with the niello to take impressions of the plates with liquid sulphur as well as impressions of their designs on damp paper. But Finiguerra discovered, by accident, that he could take equally good impressions from the plate itself; and with a mixture of soot and oil he filled the cavities of the engraving, and by pressing with a roller obtained impressions on the paper, having, as Vasari says, all the appearance of drawings done with a pen. An impression from a Pax, representing the 'Coronation of the Virgin,' dated 1452, is now in the Library at Paris, and is the oldest metal print: the original plate is still preserved at Florence. (Zani, *Materiali alla Storia dell' Incisione &c.* Parma 1802.) Bartsch, in his *Essay on the History and Discovery of the Art of taking Impressions from Engravings*, prefixed to the thirteenth volume of his work *Le Peintre Graveur*, very unwillingly admits the invention to have originated with Finiguerra, though he claims for the Germans the merit of applying it to practice for the multiplication of copies of pictures, &c.; but to this the opposing arguments of Mr. Ottley are so powerful that the subject is not likely to be again mooted. Finiguerra was followed by Baccio Baldini, a goldsmith of Florence, who, according to Vasari, employed Sandro Botticelli to design for him; but it does not appear likely that such an artist as Botticelli could have resigned himself to employment in such works as Baldini would be constantly requiring. Baccio's works were numerous, and are of course much sought after by collectors. Botticelli, a painter of eminence as well as an engraver, was a native of Florence, where he was born in 1447; he died in 1515. Among the works which he engraved from his own designs are subjects illustrative of Dante, and a number of prints of prophets and sibyls. Contemporary with him flourished Antonio del Pollajuolo, and rather later Gherardo and Robetta; but the art still remained dry in execution, and more to be admired for correctness of drawing and design than for any attempt at relief or effect. There can be no doubt that at this period it was practised at Rome, though the Venetian state and other parts of the north of Italy furnished a more abundant supply of artists, of whom Francesco Squarcione, Andrea Mantegna, Girolamo Mocetto, Marcello Fogolino, Benedetto Montagna, Bramante the architect, Gio. Bat. del Porto, Giovanni Maria, and Giovanni Antonio di Brescia were among the most eminent. The

works of Mantegna exhibit great marks of improvement on the Florentine school.

In Germany and the Low Countries the art of engraving had made extraordinary progress during the fifteenth century; and the name of Martin Schoen or Schongauer must not be forgotten. This artist, who was also a painter and goldsmith, was the father of the German school of engraving. He was a native of Ulm, where he was born about 1420. He began the practice of the art when it was in its infancy, and succeeded in carrying it to a great degree of perfection. He died at Colmar in 1488. Vasari relates that Michael Angelo, when young, was so pleased with a print by Schongauer, representing St. Anthony tormented by devils, that he copied it in colours. Israhel van Meckenem was another excellent master of this old school; he died in 1503. Albert Dürer, the most celebrated of the early engravers of Germany, was born at Nuremberg, in 1471. Skilled in many arts, and a painter of no ordinary powers, it is astonishing that, in a life not exceeding fifty-eight years, he should have succeeded also so eminently in that of engraving. On copper as well as wood his works exhibit specimens of executive excellence, which the experience of centuries has not been able to surpass. Dürer is supposed to have been the inventor of the art of etching, at least no etchings are known before those which are extant from his hand. Of his many works, his wood engravings are the most free and masterly. He died in 1528. Following Albert Dürer were Burgkmair, Schäufelein, Aldegrever his pupil, Hans Beham and his brother Bartholomew, Altdorfer, Binck, Goeding, Pencz, and Solis. Hans Holbein, who was a native of Augsburg and died in London in 1543, besides acquiring celebrity as a painter, is supposed to have been an engraver on wood, and to have executed many pieces; the most remarkable of which are the fifty-three prints called the *Dance of Death*, first published about 1530. Of the Dutch and Flemish schools, Lucas van Leyden must be considered the head. Born in 1494, at the place whence he derives his name, he was the contemporary and friend of Albert Dürer; to whom, though inferior in design, he was superior in composition. His works, which were both on wood and copper, are few in number. The Low Countries furnished a host of engravers, among whom it is unnecessary to name more than F. Floris, C. Cort, and the three Sadelers; Bloemart, who laid the foundation of the principles upon which lines become capable of expressing quality, colour, and chiaroscuro, which the French engravers afterwards improved; H. Goltzius and his pupils; Müller, and Lucas Kilian: the three last, though they handled the graver with great freedom and dexterity, fell into absurdities, which, however, were tempered and corrected by Matham and Saenredam. In the beginning of the seventeenth century the two Bolswerts appeared, whose style was much improved by the instructions of Rubens. Vorsterman, Pontius, and Peter de Jode the younger were of this school, which is dis-

ENGRAVING

tinguished for the success and correctness with which it transferred the picture to the copper, Rembrandt (1607-69), notwithstanding all his faults, claims a special notice in this place as an engraver. The 'Descent from the Cross,' and the print called the 'Hundred Guilder Print,' are extraordinary efforts of art. His portraits and landscapes are full of nature, expression, and character; and it is difficult to say whether he is more successful in his sunshine effects, than in the sober solemn twilight with which his varied subjects are enveloped. Vandyck has left a few specimens of etchings worthy of his name. Zeghers, Lutma, and above all Cornelius and John Visscher, exhibited great excellence in the art, which continued to advance under the hands of Waterloo, Jacob Ruysdael, and Paul Potter; the last of whom, in his etchings of animals, displayed a scientific acquaintance with drawing and anatomy, till his time unpractised.

We must now return to close the brief account of the Italian school, in which the appearance of Marcantonio Raimondi forms the most splendid era. Born at Bologna about 1475, he became the pupil of Francia, the great painter of that city. His master in the art of engraving is, however, unknown. We first hear of him at Venice, in 1506, whither Albert Dürer went to institute proceedings against him for pirating his prints, which had been copied by Raimondi with such wonderful accuracy that they were sold for the originals. But the proper sphere for Marcantonio was Rome, whither he soon bent his steps. There his merit soon gained him the friendship and esteem of Raphael, then in the plenitude of his glory, by whom he was employed to engrave from his designs. His first plate from a design by Raphael was the 'Lucretia,' soon after which he executed the 'Judgment of Paris.' His engravings after this master are very numerous; and though free from the blemishments of style, chiaroscuro, and local colour which the art has received since his time, such was his knowledge of drawing, such the beautiful character that pervades his works, that he is entitled to the highest rank in the art. Strutt considers him one of the most extraordinary engravers that ever lived. His school attracted to Rome artists from all parts; among whom may be enumerated Marco da Ravenna, Giulio Bonasone, Agostino de Musis, Enea Vico, and Nicolas Beatrixet. Some of the German artists whom we have named above—viz. Beham, Pencs and J. Binck—resorted to Rome for the benefit of Marcantonio's instructions. On the death of Raphael, he executed engravings of some of the works of Giulio Romano, and died in or before 1534. (Vasari, *Vite* &c. ed. Le Monnier, vol. ix.) Some of the principal pupils of Marcantonio have already been named; to them may be added Giorgio Ghisi, commonly called Mantuanus, and others of his family. Many of the Italian painters were extremely successful in engraving; among them Titian etched many landscapes; but none cultivated the art with more success than Agostino Carracci, who studied under Cornelius Cort, a

Dutch engraver, born at Hoorn in 1538. His design and execution are equally to be admired, and had he but concentrated his lights more, and attended to local colour, he would have been excelled by none. In the seventeenth century Della Bella, Callot (who, though born in France, belongs to the Italian school), Guercino, Salvator Rosa, and Claude continued the reputation of the art. At the latter end of this century was born Antonio Canaletto, originally a scene-painter, like his father Bernardo. His etchings opened an entirely new field in architectural engraving, and may be considered almost if not quite the first in which fine sparkling effects of light are introduced, and in which the darkest shadows partake of the transparency and clearness which Nature herself exhibits. J. B. Piranesi, who was born in Venice, and died in 1778, appeared about the middle of that century: he and his son Francesco, the latter born in Rome in 1748, are the most surprising architectural engravers that have ever existed, whether we consider the astonishing power or the number of their works. Their effective use of the etching needle surpassed all that has been done before or since. Of a more recent date, Volpato of Florence is a great name; besides his other works, he engraved almost all the celebrated performances of Canova with a delicacy, grace, and correctness of the first order.

The French school commenced about the middle of the sixteenth century with Noel Garnier, who was followed by many clever artists; but till the time of Louis XIV. it cannot be said to have been highly distinguished. At that epoch we have Gerard Edelinck, who, though born at Antwerp, belongs properly to the French school, and Gerard Audran. The former of these, who worked entirely with the graver, carried what is called colour in engraving to a much greater degree of perfection than had ever before been practised. The name of Gerard Audran, who engraved the well-known battles of Alexander after Le Brun, is conspicuous in the history of the art; his name, however, will descend to posterity with greater lustre from his engravings after the Italian school, and particularly those of Nicolas Poussin. Gerard Audran was born at Lyon in 1640, and died in Paris in 1703. John Audran, the last of the family who exercised the art, and nephew of Gerard, died in 1756. Nanteuil, the three Drevets, of whom Peter was the most eminent, Le Clerc, Chereau, Cochin, Beauvais, Simonneau Dupuis, and many other masters belong to this period; but Ballechon and Wille, towards the middle of the century, outstripped all that had been done by their predecessors. Wille was a German; but his residence having been chiefly at Paris, he is always ranked among the French engravers. His extraordinary powers in imitating the qualities of objects, and his extraordinary clearness in the use of the graver, entitle him to a place of the first rank in the French school, which, since the age of Louis XIV., has been more distinguished for its great mechanics!

ENGRAVING

skill, than for grace, correctness, and beauty in the higher departments of the art.

Till the middle of the seventeenth century England was indebted to foreign artists for the embellishment bestowed upon the typographical works she produced, as well as for such engravings, either in history, portrait, or landscape, as the taste of the nation required. Among the artists who visited England and made it their permanent or temporary residence were the Passes, Vaillant, Hondius, Vorsterman, Hollar, Blooteling, Dorigny, and several others. Payne, who died about 1648, and Faithorne, who executed many historical pieces and portraits in a masterly manner, were the earliest English engravers deserving mention. William Faithorne, son of the last named, was eminent as one of the earliest meszotinto engravers. This invention, which is erroneously attributed to Prince Rupert, was the discovery of a German officer, Ludwig von Siegen, born at Utrecht in 1609. He executed his first meszotint in 1642; it is a portrait of Amalia Elizabeth of Hanau. He taught his method of engraving to Prince Rupert in 1656-8, when both were residing in Brussels. Siegen was a major in the service of the duke of Wolfenbüttel, and was still living in 1676. There are seven plates by him. (Leon de Laborde, *Histoire de la Gravure en Manière Noire*, Paris 1836.)

After the two Whites, father and son, appeared Vertue, who was born in 1684. He was the scholar of Vandergucht, and from his many works must have been an artist of great industry and facility. The larger portion of his labours was confined to portraits. Vertue died in 1767, and left behind him in manuscript a history of painting and painters in England, which was afterwards published by Horace Walpole under the title of *Anecdotes, &c.* Jacob Houbraken executed some wonderful portraits at this time in England; he died in 1780. The works of Pond and Knapton can only be mentioned as continuing the history, though occasionally they possess some spirit; but Vivares, a Frenchman by birth, belonging, however, to the English school, and indeed the founder of it in landscape engraving, has in his works from the pictures of Claude shown talents which were the precursors of that pre-eminence in landscape engraving which this country has as yet perhaps exclusively possessed. Woollett carried execution to a far greater extent than Vivares, uniting with that engraver's spirit all the elegance, clearness, and finish of the French school, while to these he superadded every beauty that mechanical skill could effect. John Browne was a contemporary worthy of Woollett, whose works after Salvator, Both, and others are well executed. Sir Robert Strange distinguished himself by his great mechanical skill; the delicacy which he imparted to flesh has never been equalled. His principal engravings are from the Italian painters, especially Titian, Guido, and Correggio, and reflect great honour on the English school, which since his time has

never been deficient in producing artists of the first class, of whom one of the most eminent was William Sharp, born in London in 1746. Strange was born in one of the Orkney Islands, in 1721, and died in 1792. Sharp died in London in 1824. Since his time the names of artists of talent might be here supplied to a very great extent: we shall merely mention those of Basire, Bartolozzi, Rooker, J. Heath, Byrne, Bromley, Lowry, Earlom, Raphael Smith, Holloway, Raimbach, R. Brandard, &c. In the present day the demand of prints for the embellishment of books has produced talent which perhaps might be more nobly employed in works of a higher order. In the enumeration of masters it will be seen that the name of Hogarth does not find a place; for which our reason is that his engravings partake more of the nature of pictures transferred at once to copper, often without proceeding through the intermediate stage. The number of pure line engravers is gradually diminishing, additional difficulties having been thrown in the engraver's path through the competition of photography.

Engraving on Wood, or Xylography.—In this branch of the art the material used is a block of box or pear-tree wood, cut at right angles to the direction of the fibres, its thickness being regulated by the size of the print to be executed. The subject is drawn on the block with a black-lead pencil, or with a pen and Indian ink, taking care that the whole effect is represented in the lines so drawn. The whole of the wood is then cut away, except where the lines are drawn, which are left as raised parts; in which point it is that this mode of engraving differs so essentially from copperplate engraving, wherein the lines are cut out or sunk in the metal, instead of being raised from it. The impressions from wood blocks are taken in the same manner as from printing types. (See the elaborate *Treatise on Wood Engraving, &c.*, by W. A. Chatto, with illustrations by John Jackson, 1839.)

Engraving on Copper is performed by cutting lines representing the subject on a copperplate by means of a steel instrument ending in an unequal-sided pyramidal point, such instrument being called a *graver* or *burin*, without the use of aquafortis; which mode will be seen below, under *Etching*. Besides the graver there are other instruments used in the process; viz. a scraper, a burnisher, an oil stone, and a cushion for supporting the plate. In cutting the lines on the copper the graver is pushed forward in the direction required, being held in the hand at a small inclination to the plane of the copper. The use of the burnisher is to soften down lines that are cut too deep, and for burnishing out scratches in the copper: it is about three inches long. The scraper, like the last, is of steel, with three sharp edges to it, and about six inches long, tapering towards the end. Its use is to scrape off the burr raised by the action of the graver. To show the appearance of the work during its progress, and to polish off the burr, engravers use a roll of

ENGRAVING

woollen or felt called a *rubber*, which is put in action with a little olive oil. The cushion, which is a leather bag about nine inches diameter filled with sand for laying the plate on, is now rarely used except by writing engravers. For architectural subjects, or in skies, where a series of parallel lines are wanted, an ingenious machine was invented by the late Mr. Wilson Lowry, called a *ruling machine*, the accuracy of whose operation is exceedingly perfect. This is made to act on an etching ground by a point or knife connected with the apparatus, and bit in with aquafortis in the ordinary way.

Etching is a species of engraving on copper or other metals with a sharp-pointed instrument called an *etching needle*. The plate is covered with a ground or varnish capable of resisting the action of aquafortis. The usual method is to draw the design on paper with a black-lead pencil; the paper being damped and laid upon the plate, prepared as above, with the drawing next the etching ground, is passed through the rolling press, and thus the design is transferred from the paper to the ground. The needle then scratches out the lines of the design; and aquafortis being poured over the plate, which is bordered round with wax, it is allowed to remain on it long enough to corrode or bite in the lines which the etching needle has made. Etching with a dry point, as it is called, is performed entirely with the point without any ground, the burr raised being taken off by the scraper. Etching with a soft ground is used to imitate chalk or black-lead drawings. For this purpose the ground is mixed with a portion of tallow or lard, according to the temperature of the air. A piece of thin paper being attached to the plate at the four corners by some turner's pitch, and lying over the ground, the drawing is made on the paper and shadowed with the black-lead pencil. The action of the pencil thus detaches the ground which adheres to the paper, according to the degree to which the finishing is carried; the paper being then removed, the work is bit in in the ordinary way. *Stippling* is also executed on the etching ground by dots instead of lines made with the etching needle, which, according to the intensity of the shadow to be represented, are made thicker and closer. The work is then bit in. *Etching on Steel* is executed much in the same way as in the process on copper. The plate is bedded on common glazier's putty, and a ground of Brunswick black is laid in the usual way, through which the needle scratches. It is then bit in, in the way above described.

Mezotinto Engraving.—In this species of engraving, the artist, with a knife or instrument made for the purpose, roughs over the whole surface of the copper in every direction, so as to make it susceptible of delivering a uniform black, smooth, or flat tint. After this process the outline is traced with an etching needle; the lightest parts are then scraped out, and after these the middle tints so as to leave a greater portion of the ground, and so on according to the depth required in the several parts of the work.

Aquatinta Engraving somewhat resembles the effect of an Indian-ink drawing. The mode of effecting this is (the design being already etched) to cover the plate with a ground made of resin and Burgundy pitch or mastic dissolved in rectified spirit of wine, which is poured over the plate lying in an inclined position. The spirit of wine, from its rapid evaporation, leaves the rest of the composition with a granulated texture over the whole of the plate, by which means a grain is produced by the aquafortis on the parts left open by the evaporation of the spirit of wine. The margin of the plate is of course protected in the usual way. After the aquafortis has bitten the lighter parts they are *stopped out*, and the aquafortis is again applied, and so on as often as any parts continue to require more depth. Formerly the grain used to be produced by covering the copper with a powder or some substance which took a granulated form, instead of using the compound above mentioned; but this process was found to be both uncertain and imperfect. In the compound the grain is rendered finer or coarser, in proportion to the quantity of resin introduced. This mode of engraving was invented by a Frenchman of the name of St. Non, about 1662. He communicated it to Jean Baptiste le Prince, who died in 1781; from the latter it was acquired by Paul Sandby, who introduced it through the medium of Mr. Jukes into England. It has been practised in this country with much greater success than elsewhere.

Etching on Glass.—The glass is covered with a thin ground of beeswax; and the design being drawn with the etching needle, it is subjected to the action of sulphuric acid sprinkled over with pounded fluor or Derbyshire spar. After four or five hours this is removed, and the glass cleaned off with oil of turpentine, leaving the parts covered, with the beeswax untouched. This operation may be inverted by drawing the design on the glass with a solution of beeswax and turpentine, and subjecting the ground to the action of the acid.

Engraving on Stone or Lithography (Gr. *lithos*, a stone, and *graphein*, to write or draw). A modern invention, by means of which impressions may be taken from drawings made on stone. The merit of this discovery belongs to Aloys Senefelder, a musical performer of the theatre at Munich, where he died in 1834. The following are the principles on which the art of lithography depends: First, the facility with which calcareous stones imbibe water; second, the great disposition they have to adhere to resinous and oily substances; third, the affinity between each other of oily and resinous substances, and the power they possess of repelling water or a body moistened with water. Hence, when drawings are made on a polished surface of calcareous stone with a resinous or oily medium, they are so adhesive that nothing short of mechanical means can effect their separation from it; and whilst the other parts of the stone take up the water

ENGRAVING

poured upon them, the resinous or oily parts repel it. Lastly, when over a stone prepared in this manner a coloured oily or resinous substance is passed, it will adhere to the drawings made as above, and not to the watery parts of the stone. It was formerly thought that this country did not possess a sort of stone like that of Germany suitable to the purposes of lithography; this, however, is now known to be erroneous, as the neighbourhood of Bath abounds with it, being the white *lias*, which lies immediately under the blue. It is also found in Scotland. The ink and chalk used in lithography are of a saponaceous quality: the former is prepared in Germany from a compound of tallow soup, pure white wax, a small quantity of tallow, and a portion of lamp-black, all boiled together, and when cool dissolved in distilled water. The chalk for the crayons used in drawing on the stone is a composition consisting of the ingredients above mentioned, but to it is added when boiling a small quantity of potash. After the drawing on the stone has been executed and is perfectly dry, a very weak solution of vitriolic acid is poured upon the stone, which not only takes up the alkali from the chalk or ink, as the case may be, leaving an insoluble substance behind it, but it lowers in a very small degree that part of the surface of the stone not drawn upon, and prepares it for absorbing water with greater freedom. Weak gum water is then applied to the stone, to close its pores and keep it moist. The stone is now washed with water, and the daubing ink applied with balls as in printing; after which it is passed in the usual way through the press, the process of watering and daubing being applied for every impression. Any coloured ink may be used in lithography; hence, by using various stones, with different portions of a picture drawn on them, so arranged as to register perfectly, a facsimile of a picture can now be printed. This method of reproducing pictures or drawings is now popularly known as *Chromolithography*.

There is a mode of transferring drawings made with the chemical ink on paper prepared with a solution of size or gum tragacanth, which being laid on the stone and passed through the press leaves the drawing on the stone, and the process above described for preparing the stone and taking the impressions is carried into effect.

In Germany many engravings are made on stone with the burin, in the same way as on copper; but the very great inferiority of these to copper engravings makes it improbable that this method will ever come into general use.

Perhaps one of the greatest advantages of the art of lithography is the extraordinary number of copies that may be taken from a block. As many as 70,000 copies or prints have been taken from one block, and the last of them nearly as good as the first. Expedition is also gained, inasmuch as a fifth more copies can be taken in the same time than from a copperplate; and as regards economy, the advantage

ENLISTMENT

over every other species of engraving is very great.

Engrossing. (Fr. *grossoyer*, to write in a large hand). The writing of a deed in proper legible characters. Among lawyers it more particularly means the copying of any writing upon parchment or stamped paper. In statute law, engrossing means the buying up of large quantities of any commodity in order to sell it again at an unusually high price. [FORESTALLING.]

Enhanced. In Heraldry, bearings placed in the shield above their usual situation.

Enharmonic. In Music, a term having reference to the distinction between notes which, though different in themselves, are represented by the same key on the pianoforte. Thus a transition from G \sharp to A \flat , or from D \flat to C \sharp , is called an *enharmonic transition*.

Enigma (Gr. *αἰνύμα*). A proposition put in obscure or ambiguous terms to puzzle or exercise the ingenuity in discovering its meaning. In the present day, the enigma serves merely to beguile a leisure hour; but formerly it was a matter of such importance that the Eastern monarchs used to send embassies for the solution of enigmas. The enigma which Samson proposed to the Philistines, and the still more famous riddle of the ΣΦΙΝΞ [which see], are well known. About the seventeenth century the enigma, which had been for centuries neglected as a species of literary display, again came into favour; and in France particularly it was cultivated with so much zeal, that several grand treatises were dedicated to its history and characteristics.

Enlistment. In Military and Naval affairs, a voluntary engagement to serve as a private soldier or sailor, either for a fixed or unlimited period. Unlike the armies of the Continental nations, whose ranks are generally supplied by conscription, the troops of the British army in all its departments are obtained by voluntary enlistment. About a century ago, it was usual to engage recruits for the period of three years; but the present practice is to enlist for certain defined numbers of years. For the infantry, the period is ten years; for the cavalry and artillery, twelve years; provided the recruit be upwards of eighteen years of age, otherwise the difference between his age at enlistment and eighteen years is added to each period. No boy may be enlisted under fourteen years of age; and foreigners not British subjects can only be allowed to serve in a proportion not exceeding one in every fifty men of a battalion. The Acts regulating this subject are the 10 & 11 Vict. c. 37, 18 Vict. c. 4, and 21 & 22 Vict. c. 55. By an Act passed in 1819, called the Foreign Enlistment Act, no British subject was allowed to enter foreign service without permission from the crown; and though this Act was suspended for three successive years in favour of the troops raised in this country for the service of the queen of Spain, it is once more in full operation. [RECRUITING.]

The navy of Great Britain is also manned by voluntary enlistment; though in time of war,

or on other great emergencies, IMPRESSMENT [which see] is often resorted to. The period of engaging to serve in the navy was limited, until 1867, to the period during which the ship for which the man might volunteer should be in commission; but by an Act of Parliament of that year, a new and valuable class of men was originated, viz. *continuous service men*. These covenant to serve for a given number of years in any ship to which they may be posted. They have advantages in the way of pay, leave, pension, &c., to other sailors.

Enmanché (Fr. *resembling a sleeve*). In Heraldry, lines of about half the breadth of the chief drawn from the centre of the upper edge of the chief to the sides.

Enneagon or **Nonagon** (Gr. *ἐννέα, nine*; *γωνία, angle*). A plane rectilinear figure of nine sides and angles. The area of a regular or equilateral and equiangular enneagon is approximately 6.18182 times that of the square on one of its sides.

Enneandria (Gr.). In Botany, the name of the ninth class in the Linnean system. The flowers are hermaphrodite, with nine stamens.

Enneandrous. In Botany, having nine stamens.

Ennui. A French word, signifying the listlessness or languor which prevails during seasons of mental inactivity, satiety, or exhaustion. The Italian word *noia* corresponds to *ennui*.

Enoch, Book of. This book, from which a prophecy is quoted in the Epistle of St. Jude, is mentioned by most of the Fathers down to the time of Augustine and Jerome. It was then forgotten or lost, nor was it recovered till the celebrated traveller James Bruce brought two Ethiopian copies to Europe in 1773. In 1821 an English translation was published by Archbishop Laurence, who thinks that the book was composed within about fifty years immediately preceding the birth of Christ, and remarks the singularity that a book written so short a time previously could have 'so far imposed on the public, as to be reputed by any the genuine production of the patriarch Enoch.'

Enrollment (in Legal orthography, more properly, Inrollment). Signifies in law the registering or entering of any document or lawful act in the rolls of the chancery, or superior courts of common law, or in the records of the quarter sessions. Such enrollment was rendered necessary in different cases by statute; as a deed of bargain and sale in order to pass lands must be enrolled in one of the courts of record at Westminster, or by the clerk of the peace in any county, by 27 Hen. VIII. c. 16. Deeds to cut off the entail of a settled estate must also be enrolled in chancery under the provisions of the Fines and Recoveries Act.

Ens. A term applied by the old chemists to the essence or condensed virtues of substances.

Ens. In Metaphysics, a term denoting *entity* or *being* (Gr. *τὸ ὄν*). *Ens reale*, or positive being, is distinguished from *Ens rationis*, which exists only in idea.

Ensemble (Fr.). In the Fine Arts, a term denoting the masses and details considered with relation to each other.

Ensign (Fr. *enseigne*, Ital. *insegna*, Lat. *insignia*). The national flag carried by a ship, and usually hoisted at the peak or on a flag-staff at the stern. British men-of-war formerly carried a red, a white, or a blue ensign, according to the colour of the flag of the admiral in command of the station; but by a rule of 1864, all men-of-war carry the St. George's ensign, viz. a white ensign with a red cross and the union jack in the left-hand upper quarter. The red ensign is used by other government vessels, transports &c., and the blue ensign is abandoned to the merchant service.

Ships do not display their ensigns at sea, except in meeting strangers, when they show their national ensign. In harbour the ensign is not shown before eight A.M. nor after sunset.

The ensign hoisted with the upper corner downwards, is the signal of distress.

The English ensign is a red, white, or blue flag, having the union in the upper corner next the mast.

Ensign. A commissioned officer, lowest in rank, in a regiment of infantry. An ensign performs the usual duties of a subaltern, and the junior ensigns carry the colours of the regiment.

Ensigned. In Heraldry, any charge which is ornamented.

Entablature. In Architecture, the whole of the parts of an order above the column. The assemblage is divided into three parts: the *architrave*, which rests immediately on the column; the *frieze* next, over the architrave, being the middle member; and the *cornice*, which is the upper member: the first and last are variously subdivided in the different orders.

[ORDERS.]

Entail. [FEE TAIL.]

Entasis (Gr.). In Architecture, a delicate and almost imperceptible swelling of the shaft of a column, to be found in almost all the Grecian examples, adopted to prevent the shafts being strictly frusta of cones. This refinement, which is alluded to in the second chapter of the third book of Vitruvius, was first observed by Mr. Allston in 1814, in the Athenian edifices.

Ente (Fr.). In Heraldry, any engrafted emblazonment.

Entelechy (Gr. *ἐντελέχεια*). A peripatetic term, invented by Aristotle in order to express an object in its complete actualisation, as opposed to merely *potential* existence. [ARISTOTELIAN PHILOSOPHY.]

Enteritis (Gr. *ἐντέρας, the intestines*). Inflammation of the bowels. This disease may be occasioned by incautious exposure to cold, by acrid substances, or by hardened feces in the bowels. Its symptoms are: pain over the abdomen; thirst, heat, and excessive restlessness and anxiety; sickness; obstinate constipation; and a hard, small and quick pulse. The pain increases as the disease proceeds, especially about

ENTEROCELE

the navel; there is great difficulty in voiding the urine, which is small in quantity and high-coloured; and the abdomen is so tender as not to endure the slightest pressure. It often terminates in a few hours in mortification of a part of the intestinal canal; in which case the pain suddenly ceases, the belly becomes tumid, the pulse sinks rapidly, and the countenance acquires a peculiar ghastliness; it also proves fatal during the inflammatory stage. Favourable symptoms are: a gradual diminution of pain and of tenderness on pressure, natural evacuation by the bowels, moist skin, equal and firm pulse, and a copious discharge of urine depositing abundance of red sediment. This is a disease which requires prompt and decided treatment. Leeches should be applied over the abdomen, and the patient should be put in a hot bath, or fomented with hot water: the lower bowels should be evacuated by a glyster of castor oil and gruel, but purgatives should be avoided until inflammatory symptoms subside. Sickness should be quelled by the efferevescing draught, with a very few drops of tincture of opium. In most cases small doses of calomel and opium have been given with great advantage. When the urgent symptoms give way, and the bowels have been cleared, diaphoretic saline medicines and gentle aperients may be used, and a mild nourishing diet allowed; but great care is requisite in ascertaining that all relics of the inflammatory action are got rid of, and that it is not lurking in some one spot in a chronic form, as enteritis is often the result of old disease existing in the cavity of the abdomen.

Enterocoele (Gr. *έντερα*, and *κήλη*, *tumour*). A hernia or rupture, the contents of which are a portion of intestine.

Enterodela (Gr. *έντερα*, and *δελος*, *manifest*). The name given by Elurenberg to a section of his class *Polygastrica*, comprehending those which have a complete alimentary canal terminated by a mouth and anus.

Enterocpiplocelle (Gr. *έντερα*; *ἐπίπλοον*, *the omentum*; *κήλη*, *tumour*). A hernia or rupture containing both intestine and omentum.

Enterology (Gr.). A treatise on the bowels.

Enthymeme (Gr. *ένθύμημα*, *a thought*). In Logic, is commonly defined to be an argument having one premiss expressed, the other understood. [Logic; Syllogism.] This is the character under which the universal form of reasoning, or syllogism, generally presents itself in connected writing. For example, the following argument, if drawn out in the correct logical form, would stand thus: 'All tyrants deserve death; but Cæsar is a tyrant, therefore Cæsar deserves death.' But in the rapid diction of oratory, or poetry, it would probably be expressed either, 'All tyrants deserve death, therefore so does Cæsar;' in which case the minor premiss, 'Cæsar is a tyrant,' is suppressed; or, 'Cæsar is a tyrant, therefore he deserves death,' by suppressing the major premiss. Instances may be cited in which the enthymeme consists merely of one of the pre-

ENTOMOLOGY

misses expressed, while both the other premiss and the conclusion are to be supplied by a rapid exercise of thought. Thus in the well-known words, 'But Brutus says he was ambitious, and Brutus is an honourable man,' the last of these propositions contains a complete argument: 'What honourable men say is to be believed: Brutus is an honourable man, therefore what Brutus says is to be believed.'

Entomology (Gr. *έντομα*, *insects*, and *λόγος*).

The science of insects: the history of the organisation, habits, properties, and classification of those articulated animals which are distinguished by the presence of antennæ and of breathing organs, composed of ramified tracheæ with or without air-sacs. The name *insect*, from its etymological signification of an animal insected or divided into sections, is applicable to the greater part of the Articulate sub-kingdom, but is now restricted to the species characterised as above. The presence of highly developed organs for breathing air, together with peculiar and complex organs of sensation, is associated, as might be expected, with active powers of locomotion; and most insects, besides having articulated members for terrestrial progression, for leaping or climbing, swimming or diving, are endowed with wings, and are capable of rapid and extensive flight. The power of traversing space is given in greater fulness and perfection to the class of insects than to any other created beings on our planet. A peculiar condition of the breathing organs, and a peculiar animal tissue (chitine), which combines great strength, elasticity, and levity, co-exist in insects, and in insects only.

Those insects which have more than six articulated legs, and have the segments of the trunk free, without distinction of thorax and abdomen, which undergo no other metamorphosis than acquiring an increased number of segments after exclusion from the egg, and which lastly possess neither compound eyes nor wings, are separated by some zoologists as a distinct class, under the name *ΜΕΤΑΠΟΔΑ* [which see].

In the Hexapod insects, the body is divided into a head, thorax, and abdomen; the head supports a pair of antennæ, and contains a pair of compound, and often also simple, eyes; the mouth is provided with a labium, labrum, mandibulæ, and maxillæ; the labium and maxillæ also support peculiar feeling organs, called *palpi*. Sometimes these parts of the mouth, which are termed collectively *trophæ*, or oral organs, are distinct, and adapted to mastication: the insects thus characterised constitute an extensive primary division of the class termed *Mandibulata*. Those insects in which the trophæ are so modified as to form an instrument of suction are included in the primary division called *Huustelata*.

The Hexapod insects were divided by Linneus into the following orders:—

1. *Coleoptera*. Wings four, the upper pair hard, with a straight suture. Ex.: Beetles and earwig.

ENTOMOLOGY

2. *Hemiptera*. Wings four, the upper pair moderately hard and incumbent. Ex.: Bugs, locusts, tree-hoppers, plant-lice, &c.
3. *Lepidoptera*. Wings four, covered with scales. Ex.: Moths and butterflies.
4. *Neuroptera*. Wings four, membranaceous; anus unarmed. Ex.: Dragon-flies, May-flies, &c.
5. *Hymenoptera*. Wings four, membranaceous; anus sculeate. Ex.: Bees, ants, saw-flies, &c.
6. *Diptera*. Wings two; halteres two, in place of the posterior wings. Ex.: Flies.
7. *Aptera*. Wings none. In this order Linnaeus included not only true Apteron insects, as fleas, but also centipedes, spiders, crabs, lobsters, &c.; or the articulate animals now forming the classes *Myriapoda*, *Arachnida*, and *Crustacea*.

There is not, perhaps, any class of the animal kingdom which has been the subject of more numerous and various attempts at classification than that of insects. We have just seen that Linnaeus adopted the locomotive system as the basis of his method. Fabricius, his pupil, proposed a system founded on modifications of the structure of the mouth. Latreille endeavoured to form a natural classification of those most numerous animals from a consideration of their entire organisation. His latest system was as follows:—

Sub-class I. *Aptera*. No wings; simple eyes in most.

- A. No metamorphosis, but simple moulting, without a season of torpidity; mouth in some a simple sucker, in others mandibulate.

Order 1. *Thysanura*.

2. *Anoploura* (or *Parasita*).

- B. A complete metamorphosis, larvæ apodal; pupæ torpid; mouth haustellate, composed of an articulate sheath containing three setæ, with two scales at their base; body much compressed; the species saltatory and parasitic.

Order 3. *Aphaniptera* (or *Siphonaptera*).

Sub-class II. *Ptilota*. Wings, but sometimes not developed as such; two compound eyes, to which in many are added simple eyes.

- A. Two wings covered by two elytra, either crustaceous or coriaceous.

- a. Mandibles and maxillæ; elytra of the same consistence.

Order 4. *Coleoptera*.

5. *Dermaptora*.

6. *Orthoptera*.

- b. No mandibles nor maxillæ; mouth haustellate, composed of an articulate sheath, including four setæ; elytra membranous at their extremity in most.

Order 7. *Hemiptera*.

- B. Wings four or two; not covered by elytra.

- a. Mandibulate; wings four, membranous, and generally transparent; a small sculo (tegulum) at the base of the two anterior wings.

ENTOZOA

Order 8. *Neuroptera*.

9. *Hymenoptera*.

- b. Haustellate; wings scaly; tegula large, and thrown back.

Order 10. *Lepidoptera*.

- c. Two wings; haustellate.

Order 11. *Strepsiptera* (or *Rhipiptera*).

12. *Diptera*.

For the characters of the above orders, see the articles under their respective denominations.

Entomophaga (Gr. *ἐντομα*, and *φάγω*, I eat). A tribe of Marsupial quadrupeds, characterised by having three kinds of teeth—viz. incisors, canines, and molares—in both jaws, and the intestinal canal provided with a moderate-sized cæcum. The *Opussums* (*Didelphys*), *Bandicoots* (*Perameles*), and the genera *Myrmecobius* and *Charopus* are associated to form this group; and feed principally, though not exclusively, on insects.

Entomostracæans (Gr. *ἐντομος*, and *στρακαον*, a shell). A division of the class *Crustacea*, including those species which are covered with a thin horny tegument in the form of a shell, and consisting of one or two pieces.

Entophyte (Gr. *ἐντός*, within, and *φύτον*, a plant). A plant which grows from within another, as some rhizantha, and fungi.

Entoyer (Fr.). In Heraldry, a bordure charged wholly with lifeless things.

Entozoa (Gr. *ἐντός*, and *ζῷον*, an animal).

A name given to an extensive series of low-organised invertebrate and generally vermiform animals, of which the greater part are parasitic on the internal organs of other animals. They have colourless blood, circulated in the higher organised species in a closed system of vessels, without an auricle or ventricle; they have no respiratory organs, no articulated members for locomotion, no organs of sense. The digestive system consists either of tubes or cavities excavated in the parenchymatous texture of the body, and without an anal outlet; or of a tube with both oral and anal orifices freely suspended in an abdominal cavity. A filamentary nervous system has been recognised in the higher organised Entozoa, occasionally complicated with a ganglion near the mouth; the generative system is unisexual, hermaphrodite, or dioecious. (For the classification of the Entozoa, see *INTESTINALIA*.) The principal species of Entozoa known to infest the human body are the following: *Ascaris vermicularis*, *Ascaris lumbricoides*, *Trichocephalus dispar*, *Bothrioccephalus latus*, *Tænia solium*, in the alimentary canal; *Distoma hepaticum*, in the gall-bladder; *Acephalocystis cœdogena*, *Echinococcus hominis*, in the substance of the liver, in the omentum and cavity of the abdomen; *Filaria bronchialis*, in the bronchial glands; *Strongylus gigas*, in the kidney; *Spiroptera hominis* and *Strongylus spiniger*, in the urinary bladder; *Polystoma pinguedinis*, in the ovary; *Trichina spiralis*, in the voluntary muscles; *Cysticercus cellulose*, *Filaria medinensis*, and *Trichinella*, in the cellular tissue. The above

ENTREPÔT

is not a complete list, and the recent labours of Spencer Cobbold and other entozoologists have greatly increased our knowledge of the parasites infesting man.

Entrepôt (Fr. from Lat. *interpositum*, placed between). In Commerce, the name given in France and some other countries to a warehouse or other place where goods brought from abroad may be deposited, and whence they may be withdrawn for export to another country, without payment of any tax or duty. An *entrepôt* is, therefore, synonymous with what is called a *free port* on the Continent, and in this country with a *bonded warehouse*, that is a warehouse in which foreign products are stored under the joint locks of the king and the importer: if such products be entered for home consumption, they are free of duty till their entry; and if they be re-exported to a foreign country, they are exempted from all duty, and merely pay a small sum as warehouse rent. In popular and less correct language, the word *entrepôt* is frequently employed to designate a seaport or commercial town which exports the produce of a considerable adjacent territory, and imports the foreign articles required for its supply.

Entresol (Fr.). In Architecture. [MISCELLANEOUS.]

Entrochite (Gr. *ἐν, ἐν*; *τροχός*, a wheel). A genus of fossils consisting of the petrified arms of the sea starfish.

Entropium (Gr. *ἐν*; *τροχός*, to turn). A turning in of the eyelashes and eyelid, so as to irritate the ball of the eye.

Entry. In Law, the taking possession of lands and tenements where a man has title of entry. The term is also used for a writ of possession. Any person entitled to lands may make a formal but peaceable entry thereon, declaring that thereby he takes possession; but forcible entries with strong hand are prohibited by several statutes.

Eurmay. In Heraldry, a bordure charged with wild beasts.

Envelopes. In Geometry, curves or surfaces which are generated by the repeated intersections of given curves or surfaces whose position, form, and magnitude are allowed to vary according to some continuous law. Thus a tubular surface is the envelope of a moving sphere of constant radius, a plane curve is the envelope of its tangent, and the reciprocal of a curve is the envelope of the polar $xx_1 + yy_1 + ss_1 = 0$, of one of its points (x_1, y_1, z_1) with respect to the circle $x^2 + y^2 + z^2 = 0$.

If in the equation $u=0$ of any curve of the n^{th} order the coefficients of x and y involve any parameter a , then as the latter varies continuously, the position, form, and magnitude of the curve will in general change; when this value is increased by h , for instance, the curve will have the equation

$$u + \frac{du}{da}h + \frac{d^2u}{da^2}\frac{h^2}{1.2} + \&c. = 0,$$

or simply $u + \frac{du}{da}h = 0$

ENVELOPES

if the variation of a be infinitesimal, the last and the original equation $u=0$, therefore, we shall be able to express the coordinates of the points in which any curve intersects its consecutive, in terms of the parameter a which individualises that curve. The two equations referred to, however, are perfectly represented by the system

$$-0, \frac{du}{da} = 0,$$

from which, by eliminating a , we may clearly obtain the Cartesian equation of the envelope. Hence, the equation of the envelope results from equating to zero the discriminant of u , relative to a . If a should enter into the function u in the m^{th} degree, this discriminant will involve the coefficients of a in the degree $2(m-1)$; but these coefficients being, by hypothesis, functions of x and y of the degree n , the envelope will in general be a curve of the $2n(m-1)^{\text{th}}$ order. Again, through any point in the plane will in general pass m of the enveloped curves u , since on substituting in $u=0$ the coordinates of such a point we shall have an equation of the m^{th} degree in a , the roots of which will individualise m curves u passing through the point. On this account the curves to which u belongs are said by E. de Jonquières to form a system of the order n and index m . (Liouville's *Journal*, 1861.) Thus if the system of curves u form a pencil, then $m=1$ and the envelope will be of the order 0, in other words will degenerate to the system of n^2 points through which all curves of the pencil pass. On the other hand, if $u=0$ represent a system of right lines, then $n=1$ and the envelope will be of the $2(m-1)^{\text{th}}$ order and m^{th} class. In the latter case it may also be observed that three consecutive tangents will intersect in the same point, in other words the envelope will have a cusp or stationary point, whenever

$$u=0, \frac{du}{da}=0, \frac{d^2u}{da^2}=0.$$

Eliminating x and y from these three equations, therefore, the resulting equation will have for its roots those values of a which belong to cuspidal tangents. This resultant equation in a being, by the theory of elimination, of the $3(m-2)^{\text{th}}$ degree in a , we conclude that the envelope has, in general, $3(m-2)$ cusps. According to Plücker's equations, therefore [SINGULARITIES OF CURVES], it must also have $2(m-2)(m-3)$ double points, and $\frac{1}{2}(m-1)(m-2)$ double tangents, but no points of inflexion.

The same method is pursued in surfaces. If $u=0$ represent the enveloped or generating surface, the consecutive one will intersect it in the curve

$$u=0, \frac{du}{da}=0,$$

and the locus of this curve, or *characteristic* as it has been called by Monge (*Application de l'Analyse à la Géométrie*), will be the *envelope*. [CHARACTERISTIC.] Its equation of course

results from the elimination of a from the last two equations. The intersection of this characteristic by the next following one is represented by the equations

$$=0, \quad \frac{du}{da} = 0, \quad \frac{d^2u}{dc} = 0,$$

from which if a be eliminated, the equation of the *cuspidal edge* of the envelope will be obtained; a curve on the latter which separates its two sheets. A cusp or stationary point on this cuspidal edge will be represented by the three equations in x, y, z which result from the elimination of a from

$$u=0, \quad \frac{du}{da} = 0, \quad \frac{d^2u}{da^2} = 0, \quad \frac{d^3u}{da^3} = 0.$$

When $u=0$ represents a plane, the characteristic will be a right line, and the envelope a developable surface. If, besides being a linear function of x, y, z , u is also a rational function of a of the degree m , then the developable will be of the m^{th} class and $2(m-1)^{\text{th}}$ order, exactly as in the case of curves. The other singularities of the envelope may be easily ascertained. (Salmon's *Analytical Geometry of Three Dimensions*.)

Envoys, Ordinary and Extraordinary. Diplomatic ministers of the second order are so called. [AMBASSADOR.]

Enyo (Gr. Ένυώ). In Greek Mythology, a goddess who accompanies ARMS [which see] in battle, and delights in havoc and bloodshed. In Hesiod. (*Theog.* 273) Enyo is one of the Graie, or daughters of Phorcus and Kêto. [BELONA.]

Eocene. In Geology, one of the divisions of the tertiary period, originally suggested by the occurrence in the older tertiary rocks, so called, of a few faint dawnings of existing species of fossils (Gr. ήώς, *dawn*; καυός, *recent*). The term was originally limited by the percentage ($\frac{3}{4}$) of recent to extinct species found in a large collection of older tertiary shells of the Paris Basin, and had reference to other terms of the same kind, namely MIOCENE and PLEIOCENE. Although there are now many divisions not originally contemplated, and the percentage system is practically abandoned in the sense first intended, the terms are retained by most English and many foreign geologists. The subdivisions of the lower tertiary deposit are into UPPER, MIDDLE, and LOWER EOCENE [which see].

The eocene rocks generally are well developed in the neighbourhood of the three principal capitals of Western Europe: London, Paris, and Brussels. Each of these is, in fact, built on a special tertiary basin of this period. The rocks have thus attracted much attention; and their interest is the greater as they contain varied and interesting groups of fossils of all kinds, from the monkey down to the most minute foraminifer. The climate and arrangement of the land in the northern hemisphere must have been very different during the eocene period from that which has prevailed since.

Eolipile. [ÆOLIPILE.]

Eos (Gr. ήώς, *morning*). In Greek Mythology, a daughter of Hyperion, and wife of Tithonus. The myths about Eos explain themselves. Her mother is Euryphassa, the *broad-shining*, as Telephassa, the *far-shining*, is the mother of Europa: she is a sister of Helios and Selene, the sun and the moon; and the horses which draw her chariot are Lampus and Phaethon, the *bright* and *glistering*. In the myth of Kephalos, she is jealous of Procris, the *Deu*, and causes her death. When her son Memnon is killed, her tears fell from the sky in the form of morning dew. [AURORA.]

Epaoridaceae (Epacris, one of the genera). A natural order of shrubby Exogens, for the most part natives of Australia. They differ from *Ericaceae* chiefly in the structure of the anther, which is one-celled and destitute of appendages. The fruit of *Lissanthe sapida*, and a few other species, is eaten under the name of the Australian Cranberry; otherwise there is no plant of any known use in the order, which, however, contains many beautiful species of the genera *Epacris*, *Lysinema*, *Sphenotoma*, *Styphelia*, and *Dracophyllum*.

Epact (Gr. επάκτος, *added or introduced*). In Chronology, this term denotes the moon's age at the end of the year, or the number of days by which the last new moon has preceded the beginning of the year. The common solar year consists of 365 days, and the lunar year of only 354 days: the difference is therefore 11; whence, if a new moon fall on the 1st of January in any year, the moon will be 11 days old on the 1st day of the following year, and 22 days old on the 1st of the third year. The numbers 11 and 22 are therefore the *epacts* of those years respectively. The addition of 11 to the last epact gives 33 for that of the succeeding or fourth year; but as the lunar month never exceeds 30 days, the epact cannot exceed 30; whence 30 is deducted from 33, and the epact is reduced to 3. Of the thirty days thus rejected an *embolismic* or *intercalary* month is formed, which, consequently, occurs every third year of the lunar cycle, and gives 13 lunar months to that year. In like manner the epacts of all the succeeding years of the lunar cycle are obtained; that is to say, by adding successively 11 to the epact of the former year, and rejecting 30 as often as the sum exceeds that number, the leap years being taken account of by adding one day to each lunar month which contains the 29th of February. Supposing, therefore, the epact of the first year of the cycle to be 11, the epacts of all the 19 years of which the cycle is composed will be as follows: 11, 22, 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, 29. But the order is interrupted at the end of the cycle; for the epact of the following year, formed in the same manner, would be $29 + 11 - 30 = 10$, whereas it ought obviously to be 11, to correspond with the moon's age, all the circumstances being now supposed to be the same as they were at the commencement of the previous cycle. In

EPACT

order to understand this, it is necessary to remember that the lunar cycle of the ecclesiastical calendar is composed in the following manner: The lunations are supposed to consist of 29 and 30 days alternately, or the common lunar year of 354 days; and, in order to make up 19 solar years, six embolismic or intercalary months of 30 days each are inserted in the course of the cycle, and one of 29 days at the end. Hence it follows that after adding 11 to the epact of the 19th year of the cycle, we must reject 29 instead of 30, in order to have the epact of the following year, or the first year of the following cycle.

This method of forming the epacts is adapted to the Julian calendar, and might be continued indefinitely, if the Julian intercalation were followed without interruption, and the lunar cycle, defined as above, had corresponded exactly with the lunar motions. But the intercalation is subject to correction, and the cycle is not quite exact. Hence the epacts must occasionally be adjusted; and, generally speaking, an alteration is made on the last year of each century. In the ordinary tables of the church calendar the epacts are therefore given only for a single century; but as the Gregorian calendar now in use defines precisely the length of the year, tables, though somewhat more complicated, have been formed, which show the epacts of every future year in all time to come. They may even be found by means of an algebraic formula of no great perplexity. (See the article 'Calendar' in the *Encyclopædia Britannica*.) The epacts were invented by Luigi Ililio Ghiraldi, more frequently styled Aloysius Ililius, a physician of Naples, and author of the Gregorian calendar, for the purpose of showing the days of the new moons, and thence the moon's age on any day of the year, and consequently of regulating the church festivals. It is only in ecclesiastical computations that the epacts are ever employed; in civil affairs the civilised portion of mankind have long since laid aside the use of the lunisolar year, and regulated time entirely by the sun. In the calendar of the church of England, Easter and the other movable feasts are determined in the same manner as in the old Romish calendar, excepting that the golden numbers are prefixed to the days of the *full moons*, instead of the days of the new moons. The epacts are consequently not used. It is desirable that the custom of reckoning time by the moon, which had its origin in ignorant ages, were abandoned, and the civil year adopted for every purpose.

[CALENDAR.]

The following table shows the epacts corresponding to each year of the lunar cycle during the present century. The year of the cycle is what is usually called the golden number, which is found by the following rule: Add 1 to the date (or year), and divide the sum by 19; the quotient will be the number of cycles elapsed since the commencement of the era, and the remainder the golden number.

[GOLDEN NUMBERS.]

EPHELIS

Table of Gregorian Epacts.

Golden Number	Epact	Golden Number	Epact	Golden Number	Epact
I.	0	VIII.	17	XV.	4
II.	11	IX.	28	XVI.	15
III.	22	X.	9	XVII.	26
IV.	3	XI.	20	XVIII.	7
V.	14	XII.	1	XIX.	18
VI.	25	XIII.	12	I.	0
VII.	6	XIV.	23		

Epagoge. [INDUCTION.]**Epaphus.** [Io.]

Epaulement (Fr.). The shoulder or short parapet made at the flank of a battery, or end of a parallel, to prevent its being enfiladed.

Epaulettes (Fr.). Distinguishing ornaments worn on the shoulders by officers. In the different armies of the German states ensigns are not allowed to wear epaulettes; and hence the phrase *to obtain epaulettes* is synonymous with *to become a lieutenant*. Epaulettes were worn by officers of the British army until 1856. They are still worn in the navy, by the gentlemen-at-arms, and by deputy-lieutenants.

Epencephalic Arch (Gr. *ἐπί, upon, ἐγκεφαλον, the brain*). The bony arch which encompasses and protects the epencephalon: it is composed of the basioccipital, exoccipitals and superoccipitals, and, in general anatomy, forms the neural arch of the occipital vertebra.

Epencephalon. In Anatomy, the hindmost of the four primary divisions or segments of the brain, including the medulla oblongata, pons varolii, cerebellum, and fourth ventricle.

Epidictic (Gr. *ἐπιδεικτικός, from ἐπιδεικναι, to show*). The laudatory or encomiastic species of oratory: a branch of the Epideictic, according to the division of Aristotle *De Rhetorica*. [PANEGETIC.]

Epenthesis (Gr.). A figure of Grammar, by which one or more letters are inserted in the middle of a word; as in the Latin *retulit* for *retulit*. [METAPLASM.]

Eperua (the name of the fruit in Guiana is *eperu, a sabre*). A genus of *Leguminosæ*, one species of which, *E. falcata*, the Wallaba, is very abundant in the forests of Guiana, where it yields a hard coarse-grained timber of a bright red-brown colour, which splits so readily that it is much used for shingles, and being charged with resin is very durable.

Epheah or Epheah. A Hebrew measure of weight and capacity, containing 27·83 pints or pounds.

Ephebi (Gr. *ἐφηβοί, arrived at puberty*). A name applied particularly to the Athenian youth between the ages of eighteen and twenty years.

Epheles (Gr. *ἐπί, upon, and ἥλιος, the sun*). Spots seen upon the skin varying in colour from yellow and light brown to nearly black. Ordinary freckles are included under this head.

EPHEMERANS

The spots and markings occasioned by approximating the legs and hands too closely to the fire, go by the name of *epheles ab igne*, and older pathologists have probably applied the term to colourations of the skin which are now recognised as concomitants of a grave form of disease, *morbus Addisoni*.

Ephemerans, Ephemerines (Gr. *ἐφήμερος*, *lasting for a day*). A family of Neuropterous insects, having the genus *Ephemer* as a type. They are called *dayflies*, from the enjoyment of their last stage of existence being generally limited to twenty-four hours.

Ephemeris (Gr. *ἐφήμερος*, *a diary*). astronomical table showing beforehand the places of a celestial body. Ephemerides (the plural) of the sun, moon, stars, and planets are computed and published annually. The most celebrated of these are our own *Nautical Almanac*, the French *Connaissance des Temps*, and the Berlin *Jahrbuch*. The *Nautical Almanac* for 1868 has already appeared (June 1865).

EPHEMERIS. In Literature, a collective name for reviews, magazines, and all kinds of periodical literature.

Ephialtes (Gr. literally *one who leaps upon anything*). The nightmare. This affection, consisting of horrid dreams, with a sensation of great pressure upon the body, and of fruitless endeavours to escape and call for help, is generally symptomatic of indigestion, or of overdistension of the stomach. For its relief, opening medicine, and sometimes an emetic, are often required, and careful abstinence from all that promotes dyspepsia, especially supper-eating. [PNIGALION.]

Ephod (Heb.). An ornament worn by the Hebrew priests. That of the high priest was composed of gold, blue, purple, crimson, and twisted cotton; on the part which came over his shoulders were two large precious stones, on which were engraven the names of the twelve tribes of Israel, six on each stone. The ephods worn by the ordinary priests were of fine linen.

Ephori (Gr. *ἐφοροι*). In Ancient History, the title of a class of magistrates common to many of the Dorian states of Greece, but more particularly known in reference to the political constitution of Sparta, where the ephors held the supreme power in the state. The Spartan ephors were five in number, and were elected annually from the body of the ruling caste, and not from any particular tribe. Besides their judicial authority, they exercised a control over the functions of the kings and the senate, and sometimes recalled the former from their foreign expeditions, and demanded an account of their proceedings. The executive power likewise was almost wholly in their hands.

Epic (Gr. *ἔπος*, *a word or tale*). If a name, which has been loosely applied to poems differing widely from each other in many important features, admits of definition, an epic may be defined to be a poem which relates the history of some one event or one series of events which, apart from what precedes or follows them, may be regarded as a whole. But it may fairly be

EPIC

doubted whether any idea of such unity of conception or execution was present to the minds of the poets under whose hands the earliest epic poems grew up into shape. Every race or tribe has had its legends or myths; but not all tribes have seized on some one or more of its prominent myths, and moulded them into long narrative poems, like those of the Hindus, the Greeks and the Teutons.

Of the Greek epics, two only, the *Iliad* and the *Odyssey*, have come down to us: yet in the eighth century before the Christian era there existed a large number, among which may be named the *Capture of Œchalia*, the *Return of the Heroes from Troy*, the *Epigoni*, the *Æthiopis* of Arctinus, &c. On these poems, Mr. Grote (*History of Greece*, part i. ch. xx.) remarks that, though they served as food for the curious, and as storehouses for logographers, tragedians and artists, they 'never seem to have acquired very wide popularity even among intellectual Greeks.' If it is not easy to account fully for so singular and significant a fact, we may at least note the difference between epic poems whose date and authorship are unknown, and epics which have proceeded from some one author in an historical age. A vast gulf separates the Homeric poems from the *Æneid* of Virgil. As compared with the *Iliad* or the *Odyssey*, the construction of the *Æneid* is artificial, and throughout the poet is seen executing a self-imposed and a somewhat laborious task. In the former there is no appearance of effort, while there seems to be an overwhelming amount of evidence to show that the two poems could not have been the work of any one man. If the greater unity of the *Odyssey* may be taken as proving that a single poet has cast the tale into its present shape, the *Iliad* in strictness of speech exhibits no unity at all. It is popularly supposed to relate the tale of the Trojan war; in reality it professes to speak only of the wrath of Achilles and its results, and it does not fulfil even this promise. (*Edinburgh Review*, January 1866, p. 137 &c.) As Mr. Grote has shown, the first book belongs to a poem which was an *Achilleis*; the second book belongs properly to an *Iliad*; and thenceforth the two poems are put together by a process of dovetailing which is not always free from clumsiness. But the whole action of the *Iliad* is only a single episode in the tale of Troy; and the tale of Troy itself, in Professor Max Müller's belief, 'is but a repetition of the daily siege of the East by the solar powers, that every evening are robbed of their brightest treasures in the West.' Thus much at least is clear, that, although for the Greek these poems had, in Mr. Grote's words, the 'weight and solemnity of history and religion combined,' they are for us utterly unhistorical. After a careful examination, Mr. Grote deliberately concludes that 'as the possibility of an historical Trojan war cannot be denied, so neither is the reality of it be affirmed.' But the improbability of the former is enormously increased when we find that a marvellous pa-

EPICALYX

rallielism runs through the great epic poems of Greece, India, and Germany; that the *Odyssey* reproduces the main incidents of the *Iliad*; and that these, with many names, phrases, and turns of thought, are to be found also in the Vedic poems, as well as in the Saga of the Volsungs, and the Lay of the Nibelungs. Without going, therefore, at length into the vexed question of the composition of the Homeric poems, thus much may be affirmed without fear of contradiction, that they were composed in an age which had no contemporary history; that they were not reduced to writing until long after they had been composed; and that they comprise narratives many of which may, and some of which, it would seem, must, have existed once as separate poems. From this the conclusion seems to follow that a real epic is the expression of national thought, working on materials common to the whole Aryan family of nations, and possibly not wholly confined to these. Hence there would appear to be a close and inseparable connection between epic poetry and mythology. The epic is the genuine growth of a mythopoeic age; while the so-called epics of historical periods are either mere imitations, or poems which have an epical character chiefly or only as narrating a real or alleged history. The latter may exhibit the genius of a single poet; the former are of the highest importance as throwing light on many stages in the history of the human mind, for which they furnish the only evidence. To the former class belong the great poems of Milton, Tasso and Dante. The Spanish *Romanos of the Cid* approaches nearer to the character of the *Nibelungen Lied*, and seems to exhibit some of the intermediate phases through which the *Iliad* passed before it was brought into its present shape. The French epics, as the *Henriade* of Voltaire, &c., are more thoroughly artificial than the other poems of modern times which have been entitled *epics*.

The Finnish epic of Wainamoinen is based on cosmogonical myths, which in Greece found their expression in the Orphic and Hesiodic theogonies.

Epiccalyx (Gr. ἐπὶ, and κάλυξ, a flower-cup). In Botany, the involucre or series of envelopes external to the calyx, such as occur in *Malva*.

Epiccanthis (Gr.). In Anatomy, the angle of the eye.

Epicaridans, Epicarides (Gr. ἐπὶ, upon, and κάρι, a shrimp). A family of Isopodous or equal-footed Crustaceans, which are parasitic upon shrimps.

Epicarp (Gr. ἐπὶ, on, and καρπός, fruit). In Botany, the outermost layer of the pericarp.

Epicedium (Gr. ἐπιτάφιος, from ἐπὶ, and τάφος, grief). In Poetry, an elegiac poem on the occasion of a funeral solemnity in honour of some deceased person.

Epicene (Gr. ἐπίκυνος, common). In Grammar, a name used to designate those nouns which may be applied to objects masculine and feminine indifferently.

EPIPUREANS

Epicranitis (Gr.). In Ancient Architecture, a tile forming the cyma of the cornice. The term is used in a celebrated Athenian inscription brought to this country by Dr. Chandler, and now in the British Museum.

Epicureans. Followers of the tenets of Epicurus, a philosopher who lived from a.c. 337 to a.c. 270, and taught during the latter half of his life at Athens. The name of Epicureans has become the general designation of those who, either theoretically or practically, make pleasure the chief end of life and the standard of all virtue. Epicurus was the first philosophical teacher who deserted the lofty idea of science which Plato and Aristotle had striven to develop. Truth is, with him, no longer an object worth pursuing for its own sake, but only in so far as it contributes to the peace of mind of its possessor. Hence, though he retains the threefold division of philosophy into ethics, physics, and dialectics (in Epicurean language, *canonics*), he assigns the two latter a place subordinate to the first, and bestows on them a mere cursory treatment. But we should greatly wrong Epicurus if we represented the gratification of the sensual appetites to be the object proposed by him to the wise man. The happiness which he regards as the true end of existence is rather a species of quietism, in which the philosopher, protected by his knowledge from all fear of injury from the powers of nature, and by the laws from the assaults of his fellow-creatures, holds himself open to all the pleasurable sensations which the temperate indulgence of his ordinary appetites, the recollection of past enjoyments, and the anticipation of future, are sufficient abundantly to furnish. In order to support his imaginary wise man in this tranquillity, he deemed it necessary to show that the apprehensions which beset mankind, of death, of the power and anger of the gods, and the like, are wholly unfounded. For this purpose he made use of the physical doctrine of Democritus; a system of atomic materialism, which makes all existences to arise from the concourse of minute particles of matter—the soul among the number, which is consequently, at the moment of death, resolved into its constituent elements. The mental philosophy of Epicurus was of a similar stamp: all our mental powers are resolved into sensation, immediate or recollected; and sensation, under both its forms, consists in the influx of certain extremely fine films, which are perpetually, as it were, sloughed from external objects, and find their way through the organs of sense to the soul. The gods of the Epicureans bear no relation to any part of their system: they are beings sprung, like men, from the concourse of atoms, and differing from them only in their superior blessedness and tranquillity, shown in their entire separation from the care and government of the world. The followers of Epicurus were numerous, especially among the Romans. Little more, however, than their names are recorded; with the exception of Lucretius, who, in his well-known poem, *De Rerum Natura*, illus-

EPICYCLE

trates and defends the physical and religious tenets of his master. In modern times, Gassendi, an atomic philosopher of the seventeenth century, has published an able statement of the Epicurean system, under the title of *Syntagma Philosophica Epicuri*. (See also Diogenes Laërtius, *Vit. Phil.* l. x.; and Cicero's philosophical writings generally: also Ritter, *Gesch. der Philos.* b. x.: and for a list of the Epicureans, *Fabricii Bibliotheca Græca*, vol. iii. ed. Harles.)

Epicycle (Gr. *ἐπί, upon*, and *κύκλος, circle*). In the Ancient Astronomy, a circle having its centre on the circumference of another circle. It was a favourite axiom of the Greek astronomers, that all the celestial motions must be circular and uniform. The phenomena of the stations and retrogradations of the planets were apparently inconsistent with this supposition; and in order to explain them, Apollonius of Perga imagined the ingenious apparatus of *epicycles* and *deferents*. He supposed the planet P to move uniformly in the

small circle or *epicycle* PAB, the centre of which is carried uniformly forward along the circumference of the large circle or *deferent* CDE, of which the earth occupies the centre E. Hipparchus, having discovered the eccentricity of the solar orbit, supposed the motions to be performed in eccentric circles. Ptolemy, the celebrated founder of the system which astronomers followed till the days of Copernicus, adopted the hypotheses both of Apollonius and Hipparchus; that is, he supposed the earth E to be placed at a small distance from the centre of the deferent circle (which consequently was called an *eccentric*), and the planet to move uniformly in the epicycle, the centre of which also moves uniformly in the deferent. By means of these suppositions, and by assigning proper ratios (determined by observation) between the radius of the deferent and the radius of the epicycle, and also between the velocity of the planet in its epicycle and the velocity of the centre of the epicycle on the deferent, he was enabled to represent with considerable accuracy, indeed with all the accuracy which the observations of that time required, the apparent motions of the planets, and particularly the stations and retrogradations which formed the principal object of the researches of the ancient astronomers. As a first step towards connecting the two sciences of astronomy and geometry, the system of epicycles does infinite honour to its inventors; and it ought to be borne in mind that it was never given out by Ptolemy as anything else than a mere hypothesis for representing the apparent celestial motions, or, as he expresses it, for *saving the appearances*.

Epicycloid. The curve traced by a point on the circumference of a circle which rolls on the convex side of a given fixed circle. The epicycloid belongs to the large family of curves known as *roulette*s; it is not necessarily a transcendental curve; in fact it is always of finite order, when the circumferences of the

EPIDERMIS

two circles are commensurable. The normal of the epicycloid may be easily constructed; it always coincides with the line which joins the generating point to the corresponding point of contact of the two circles. The evolute of the epicycloid is a similar epicycloid, the radii of the circles being merely altered in a certain ratio. When the circles are equal, the epicycloid is similar and similarly placed to the pedal of the fixed circle with respect to a point in the circumference. [PEDAL.] The curve is in fact the cardioid which is the inverse of a parabola. The equations of epicycloids are easily found, and are given in all text-books.

The epicycloid was invented by the celebrated Danish astronomer Romer, the discoverer of the progressive motion of light, who proposed this curve, about the year 1674, as the proper form of the teeth of wheels, in order to destroy the friction. Newton, in the first edition of the *Principia*, gave its rectification; and Halley, in the *Philosophical Transactions*, No. 218, showed how its quadrature depends on that of the generating circle. The other principal properties of the curve were discovered and demonstrated by John Bernoulli.

Epidemie (Gr. *ἐπίδημος, among the people*). An infectious or contagious disease, which attacks many people at the same period and in the same country, 'rages for a certain time, and then gradually diminishes and disappears, to return again at periods more or less remote.' Thus Asiatic cholera, influenza, scarlet fever, measles, &c., frequently appear as *epidemics*; that is, are found to prevail in certain parts of a country, while the adjacent districts are free from their ravages. It is essential to the medical notion of an *epidemic* that it be of a temporary, in contradistinction to a permanent character, though isolated cases may occasionally be observed in districts once visited by the epidemic. It differs from *endemic*, inasmuch as the latter class of diseases are of a more permanent nature, and prevail only among certain people and in certain districts.

Epidermic Method. The application of medicinal substances to the skin, such as baths and lotions. But the term is more generally used in reference to the affection of remote parts of the system by external applications, aided by friction, and to this the term *iatroleptic method* (from the Greek *ἰατρειν, to cure*, and *ἄλκιον, to anoint*) has been especially applied. In this way mercurial ointment is frequently employed; and opium, belladonna, iodine, and some other powerful remedies have been similarly used.

Epidermis (Gr. *the outer skin*). In Anatomy, the cuticle or scarf skin. It is an albuminous membrane.

EPIDERMIS. In Botany, the cellular integument, or the exterior cellular coating of the bark, or leaf, or stem of a plant. It is composed of cells, compacted together into a stratum, varying in thickness in different species, and is often readily separable by gentle violence.

EPIDIDYMS

Epididymis (Gr. *ἐπιδιδυμῖς*). In Anatomy, a body formed by convolutions of the commencement of the sperm-duct or *vas deferens*, lying upon the testicle, and more or less closely attached to that gland.

Epidote (Gr. *ἐπίδοτος*, *increase*; because the base of the primary form undergoes an increase in some of the secondary forms). A mineral which has received several names. It consists essentially of silicate of alumina with silicate of lime (*Zoisite* or calcareous Epidote), or with silicates of lime and of protoxide of iron (*Pistachite* or calcareo-ferruginous Epidote), or with silicates of lime and of protoxide of iron and manganese (Manganous Epidote). Its colour is usually various shades of green, yellow and red. It occurs in granite and other igneous rocks, and in various crystalline slates.

Epigeous (Gr. *ἐπίγειος*, *on the earth*). In Botany, a term used to denote plants which grow close to the earth.

Epigastric Region (Gr. *ἐπιδαστρικόν*, from *γαστήρ*, *the stomach*). That part of the abdomen which is over the stomach. It is also called the *epigastrium*.

Epigenesis. In Physiology. [EVOLUTION.]

Epiglottis (Gr. from *ἐπί*, and *γλῶττα*, *the tongue*). An oval cartilage at the root of the tongue, which closes upon the superior opening of the larynx; its upper extremity is loose, and elevated by its own elasticity: it closes the aperture of the larynx when the tongue is drawn back in the act of deglutition. Its base has a ligamentous attachment to the base of the tongue, the thyroid cartilage, and the os hyoides.

Epigoni (Gr. *ἐπίγονοι*, *the after-born*). The collective appellation of the sons of the seven Greek princes who conducted the first mythical war against Thebes without success.

Epigram (Gr. *ἐπίγραμμα*, *an inscription*). In Poetry, a short poem or piece in verse, which has only one subject, and finishes by a witty or ingenious turn of thought; or, to use a more general definition, an interesting thought represented happily in a few words.

The first of these definitions, although tolerably correct as to the modern epigram, differs, as it will be seen, widely from the original sense of the word in Greek. The Greek epigram was, in the first instance, a short collection of lines actually inscribed on a monument, statue, fountain, &c.; and the word was thence transferred to such short poems as might serve for inscriptions: of such the collection termed the *Greek Epigrams* is almost wholly composed. Their general characteristic is perfect simplicity, and the seemingly studied absence of that point which characterises the modern epigram. But probably this seeming pointlessness is due to our ignorance of the full circumstances under which they were written, and to which they make reference or allusion. Many modern epigrams which appear excessively harsh and bitter would certainly have been dull and flat to Cicero or Cæsar, from mere ignorance of the double play of thought which gives point to words;

EPILEPSY

seemingly colourless. Hence it would seem that the first and the indispensable requirement of an epigram is not brevity, or sharpness, or honey (which are secondary and subordinate attributes), but *antithesis*. The more sudden the blow, the more striking is the epigram; hence the epigram which is confined to the couplet makes the nearest approach to perfection of its kind. Epigrams are almost wholly in one form of metre, the elegiac.

In the poetry of classical Rome, the term *epigram* was still somewhat indiscriminately used to designate short pieces in verse; but the works of Catullus, and still more the well-known collection of the *Epigrams of Martial*, contain a great number which present the modern epigrammatic character; and Martial has, in fact, afforded the model on which the modern epigram has been framed. In this class of composition, and especially where the turn of thought is satirical, the French writers have been far more successful than those of any other nation; and the term *piquant* seems expressly invented to designate the peculiar force of those epigrammatic sallies of fancy of which their literature is full.

Epigraph (Gr. *ἐπιγραφή*, *an inscription*). Also termed *Motto*. In Literature, a citation from some author, or a sentence framed for the purpose, placed at the commencement of a work or of its separate divisions.

Epigynous (Gr. *ἐπί*, and *γυνή*, *a female*). A term used in Botany to denote any organ growing upon the summit of the ovary. It is employed to express the condition of the outer whorls of the flowers, when they adhere to the ovary, so that the outer parts alone are free, and appear seated on it, as in *Umbellifers*, *Campanulas*, &c.

Epilepsy (Gr. *ἐπιληψία*, *a seizure*). This disease is also called the *falling sickness*, from the suddenness of its attack. The *morbus comitialis* of the ancient Romans was doubtless epilepsy. It is attended by convulsive, stupor and frothing at the mouth. It comes on by fits, which after lasting a certain time go off, generally leaving a degree of lassitude and drowsiness. Where fits are symptomatic of irritation in the prime viæ, from worms, or indigestible and noxious food, or poisons, or when they arise from the suppression of long-accustomed evacuations, the treatment is sufficiently obvious; so also in cases where they result from a blow, wound, or fracture, or from diseased bone, they may be relieved by proper surgical aid. True epilepsy, however, is always indicative of something essentially wrong in the nervous system; and where it arises from hereditary disposition, or comes on about the age of puberty, where the fits are frequent, and cannot be referred to any apparent cause, an unfavourable opinion must be formed respecting its termination, which, if not in apoplexy, is commonly in mental alienation or imbecility. Yet the most unpromising cases have in a few rare instances ended well; that is, they have not recurred after violent pains

EPILOGUE

or eruptive disorders. It sometimes happens that certain symptoms precede the attack; and among them a sense of coldness proceeding from some part of the body towards the head and called *ura epileptica*, with palpitation, flatulency, and slight stupor, are the most common. In such cases a brisk emetic, a large dose of opium and ether, a cold bath where it may be ventured upon, or anything which produces a sudden shock upon the system, has prevented the fit. The most effective remedial treatment seems to be that which is directed to the diminution of nervous irritability by tonics. Bark, quinia, cascarrilla, valerian, and some metallic salts, such as sulphate of iron, zinc, or copper, arsenate of potash, or the arsenical solution, and especially nitrate of silver, may be used; but the chance of permanently disfiguring the patient by the leaden hue which this last salt often communicates to the skin, should induce practitioners to be most scrupulous in the selection of this remedy. It is said that a violent scald or burn, or great alarm, as from a fire, a fall, or other accidents, have sometimes relieved the system of this complaint; and hence perhaps the superstitious notions which have attached to its cure by charms.

During an epileptic fit, nothing can be done for the relief of the sufferer except taking care that he does not injure himself, and relieving him of any part of his dress which may tend to compress the vessels of the head; the paroxysms, however, very frequently occur in the night.

Epilogue (Gr. *ἐπίλογος*). In Dramatic Poetry, the closing address to the audience at the end of a play.

Epimeral (Gr. *ἐπί*, and *μῆρος*, a thigh). In Zoology, the part of the segment of an articulate animal which is above the joint of the limb.

Epimetheus. [PROMETHEUS.]

Epiphany (Gr. *ἐπιφάνεια*). A church festival, signifying the manifestation of Christ, and referring to the appearance of the star which announced His birth to the Gentiles. It is observed on January 6, the twelfth day from Christmas.

Epiphora (Gr. from *ἐπί*, and *φέρω*, I bear). A disease occasioned by a superabundant secretion of tears.

Epiphyllous (Gr. *ἐπί*, and *φύλλον*, a leaf). In Botany, something inserted upon a leaf.

Epiphysis (Gr. *ἐπιφύσις*, an outgrowth). A process of a bone separated at first by a layer of cartilage from that to which it is attached.

Epiphyte (Gr. *ἐπί*, on, and *φύω*, I produce). A plant which finds a resting-place upon the surface of other plants, e.g. many mosses and orchids, as distinguished from parasites which draw sustenance from their foster plants.

Epiplocele (Gr. *ἐπιπλοή*, the omentum, and *κῆλη*, tumour). A hernia or rupture formed by a protrusion of the omentum.

Epipleom (Gr.). The *OMENTUM* [which see].

EPISCOPACY

Episcopium (Gr. *ἐπισκήπτεον*). In ancient Architecture, the upper order of the scene in a theatre.

Episcopacy (Gr. *ἐπισκοπία*, an over-see). The government of a church by three distinct orders of ministers—bishops, priests, and deacons. The nature of the argument upon which this constitution is defended will be clearly seen in a quotation from Bishop Short's *History of the English Church*. Speaking of the points at issue between the Presbyterians and the Church party in the reign of Elizabeth, he asks, 'Were there three distinct orders in the primitive church? and if so, was the right and office of ordaining peculiar to the highest of these?' He then proceeds to argue thus: 'In the apostolical history, as contained in the New Testament, these questions are not clearly answered, and there is much indistinctness about the names of *bishop* and *priest* or *elder*; but if we suppose, by way of hypothesis, that there were bishops, priests, and deacons, we shall find no statements which cannot be easily reconciled with the supposition. As we proceed with ecclesiastical history, those same traces become more decisive, till we find that at an early period the questions are both answered in the affirmative; and we infer, therefore, that unless it can be shown that a change in this particular took place, we may presume that the same ecclesiastical constitution existed from the time of the apostles. A Presbyterian might argue that in the apostolical history of the New Testament there is nothing which militates against the hypothesis of the two orders only, at least nothing which proves the point; that St. James might have been the chief elder, the moderator of the church of Jerusalem; that Titus and Timothy might have held no higher office than that of dean in a cathedral church, or archdeacon in a diocese; and that as the presbytery had the power of ordaining, they, as its superintendents, were directed by St. Paul to set all things in order. But then this hypothesis does not account for the introduction of episcopacy, without even a hint from the historians that any alteration in the church government was effected. When to this it is added, that there never existed a church without episcopacy till the Reformation, the proof seems as strong as moral proof can be that it is most probable that episcopacy is derived from the times of the apostles.' He adds in a note: 'The argument concerning the name of bishop is frequently mistaken. There is no doubt that *ἐπισκοπος* is equivalent to *πρεσβύτερος* in the New Testament; but then the terms used in the New Testament for *bishop* are *ἐπίσκοπος* or *ἐγγελλος*. The concession, therefore, of the use of the name *ἐπισκοπος* proves nothing. The Presbyterian is forced to say, that the order equivalent to that of the apostles does not now exist in the church, and to explain *ἐγγελλος* by the *chief pastor of the church*. So that the argument from the names is rather in favour of episcopacy.' It will be observed that this defence mainly relies upon the argument from antiquity and immemorial

EPISCOPALIA

usage; and this is the authority to which the Episcopalian always pays the highest regard when the Scriptures do not appear to be decisive. But the Presbyterians and Independents very generally take a different ground, and argue in the words of Dr. MacLaine, the translator of Mosheim—that Christ, by leaving this matter undetermined, has of consequence left Christian societies a discretionary power of modelling the government of the church in such a manner as the circumstantial reasons of times, places, &c. may require; and therefore the wisest government of the church is the best and the most divine; and every Christian society has a right to make laws for itself, provided that these laws are consistent with charity and peace, and with the fundamental doctrines and principles of Christianity.'

Episcopalia or **Onera Episcopalia** (Lat.). In Ecclesiastical History; synodals or other customary payments from the clergy to their bishop or diocesan, which were formerly collected by the rural deans, and by them transmitted to the bishop. (*Mon. Ang.* iii. 61.)

Episodo (Gr. ἐπεισόδιον). This word in its original sense denotes those parts of a classical drama which are between the entrances, εἰσόδος, of the chorus; and thence, by analogy, has the signification which has adhered to the derivative word in modern use—an incidental narrative or digression in a poem, more or less connected with the main plot, but not essential to its development.

Epispastile (Gr. ἐπισπαστικός, *attracting*). A term applied to substances which raise a blister upon the skin.

Episperm (Gr. ἐπί, and σπέρμα, *a seed*). In Botany, the testa or integuments of a seed.

Epistates (Gr. *a president*). The title of the presidents of the two great councils of the Athenians, viz. the Ecclesia and the senate of the Five Hundred. They were elected from the proedri of the ecclesia and senate, and their office lasted for one day, during which they kept the public records and seal.

Epistaxis (Gr. *a dripping*). Bleeding at the nose. In young persons, and where it is produced by accidental causes, this is of no consequence; unless, indeed, it should be very profuse, and then the topical application of cold and of styptics, especially a strong solution of alum, or a plug of lint properly introduced, will check it; but when it occurs frequently in advanced life, and is independent of nasal disease, it is apt to indicate fulness of the vessels of the head. It is a dangerous omen in disorders of great debility, and more especially in putrid fever.

Epistle (Gr. ἐπιστολή). In Ecclesiastical language, this word denotes those addresses by apostolical writers to their Christian brethren which are contained in the canon of Scripture; a few others, either spurious or of high antiquity, although not comprised in the canon, are also so denominated. The Epistles of St. Paul, and others in the New Testament, are not arranged according to their date, but, in

EPITHELIUM

all probability, according to the views which those who arranged the canon entertained of the relative importance either of the writings themselves, or of the parties to whom they are addressed. Thus the Epistles of St. Paul to the different churches, and the Catholic Epistles of St. John (i. e. addressed to the universal church), are ranked before their Epistles to individual Christians. An exception to this rule is found in the Epistle to the Hebrews, which is placed last among those commonly ascribed to St. Paul, and seems to have been admitted into the canon at a later period. The practice of reading a portion of an Epistle in the service of the church is extremely ancient, and is noticed by Justin in his *First Apology*.

Epistylum (Gr. ἐπιστύλιον). In Architecture, the same as ARCHITRAVE [which see].

Epitaph (Gr. ἐπιτάφιος, sc. λόγος, from τάφος, *a tomb*). Literally, an inscription on a tomb. Among the Greeks this honour was paid only to the tombs of heroes, as in the case of Leonidas and his gallant comrades. (*Her.* vii. 228.) The Romans were the first to deviate from this course. Every Roman family who consecrated a tomb to their relations had the privilege of inscribing an epitaph thereon; and as their tombs were usually situated on the highway, the attention of passers-by was sought to be arrested by the words 'sta viator,' the formula with which their epitaphs were prefaced.

At what period sepulchral inscriptions came into use in England, has not been precisely ascertained; though there can be little doubt that this practice was introduced by the Romans at the period of their invasion of Britain. During the first twelve centuries of the Christian era, the monumental inscriptions of this country were all written in Latin. About the thirteenth century, the French language was adopted, and continued to be used for this purpose till the middle of the fourteenth century; at which time monumental inscriptions in the vernacular tongue became common, though the clergy and learned of that time, as might have been expected, still preferred the Latin, as their more familiar idiom. The modern English, French, and German epitaphs, of which several collections have been made, exhibit every variety of style and sentiment.

Epithalamium (Gr. ἐπιθαλάμιον). A nuptial song, sung by a chorus of boys and girls when the bride and bridegroom entered the bridal chamber, and again on the first morning after the marriage. The most perfect examples of this species left to us are by Theocritus and Catullus.

Epithelium (Gr. ἐπί, upon; θηλή, *a teat*). In Anatomy, a thin and delicate kind of cuticle, like that which covers the nipple. The term is now confined to the innermost layer of the internal cavities and canals of the body, which is analogous to the cuticle of the outer surface. The epithelia of the mucous membranes consist of the secreting cells of those surfaces, and are either *tesclated*, *cylindrical*

EPITHET

droid, or ciliated. The tessellated, or pavement epithelium, is composed of flat, roundish, or polygonal cells, arranged in one or more layers, and is spread over the mouth, pharynx, and œsophagus; it is the kind of epithelium which most nearly resembles the external cuticle. A tessellated epithelium also lines most of the serous and synovial membranes, the vascular system, and the secreting tubuli and ducts of many glands. The *cylindroid* epithelium is composed of close-set cells of a conical or cylindrical form, and extends from the cardiac end of the stomach along the intestinal tract to the anus, and lines the principal gland-ducts which open upon this surface. It lines the ureters and urinary bladder.

The cells of the ciliated epithelium support at their free extremities fine pliant hair-like appendages called *cilia* which are in constant and rapid vibration: this kind of epithelium lines the whole respiratory tract, the interior of the cerebral ventricles, the uterus and oviducts, and the Malpighian capsules of the kidneys of the Batrachia.

Epithet (Gr. *ἐπίθετον*, something imposed upon another). In Rhetoric and Composition, a term employed in an adjective sense to express an attribute or quality of another substantive term.

Epitome (Gr. *ἐπιτομή*, a cutting short). In Literature, an abridgement: a work in which the contents of a former work are reduced within a smaller space by curtailment and condensation. In the later classical period, extending through the declining age of the Western Empire, the practice of epitomising the writings of older writers, especially in history, became very prevalent; and while some regard the works of Justin, Eutropius, and similar writers as having preserved to us much historical knowledge which would otherwise have been lost, others have maintained that these laborious compilers have done great mischief to literature, inasmuch as the voluminous works which they abridged were superseded by their more popular and cheaper compendia, in an illiterate age, and have from that cause for the most part perished. [ABRIDGMENT.]

Epitrochoid (Gr. *ἐπί; τροχός*, a wheel; and *εἶδος*, form). The curve traced by a point in the plane of a circle which rolls on the convex side of a fixed circle. The curve thus generated belongs to the family of roulettes, and becomes an epicycloid when the generating point is in the circumference of the rolling circle. When the two circles are equal, the epitrochoid becomes similar to the pedal of the fixed circle with respect to a certain fixed point in its plane. [ROULETTE.] But the pedal being always the inverse of the reciprocal of the primitive curve [PEDAL], the epitrochoid in this case must be the inverse of a conic with respect to one of its foci, which latter is a curve of the fourth order, belonging to the family of Cartesian ovals, and known as the *limaçon*. [LIMACON.] Epitrochoids are in general transcendental curves; it is only

EQUANT

when the circumferences of the fixed and rolling circles are commensurable that the epitrochoid returns into itself and becomes an algebraical curve.

Epizoon, **Epizoa** (Gr. *ἐπί*, upon, and *ζῷον*, animal). The name of a class of parasitic animals, which chiefly infest fishes, and of which the Linnæan genus *Lernæa* is the type.

Epizootic Diseases (Gr. *ἐπί*, upon, and *ζῷον*). When diseases prevail among inferior animals, they are said to be *epizootic*, corresponding to *epidemics* among men.

Epoch (Gr. *ἐποχή*, from *ἐπείχω*, I stop). In Astronomy, one of the elements of a planet's orbit.

EPOCH. In Chronology, a fixed point of time from which dates are numbered, or at which a new computation begins. [ÆRA.]

Epode (Gr. *ἐπῶδες*, something added to the *ᾄδη*, or ode). In the strophic choruses of the Grecian drama, the last portion following the strophe and antistrophe is so called. The name of *Epodes*, applied to a book of Horace's poems, merely signifies supplementary odes.

Epopee. [EPIC.]

Epopt. The name, *ἐπόπτης*, was given to all who were initiated in the Eleusinian Mysteries. [MYSTÆRES.]

Epotides (Gr. *ἐποτίδες*, from *ὤς*, *ὠτός*, an ear). In ancient Naval Architecture, two thick blocks of wood, resembling ears, one on each side of the prow of a galley, for warding off the blows of the rostra of an enemy's vessel.

Éprouvette (Fr.). In Gunnery, a machine for proving the strength of gunpowder. After the powder has been incorporated, a small mortar is placed vertically, and projects upwards a shot attached to a rod, which having ascended to its extreme height is prevented from descending by a small pawl catching in a rack. The height to which the shot ascends determines the strength of the powder. After the manufacture is complete, a shot is projected from a mortar, and by its range gives the strength of the powder.

Epsom Salt. Sulphate of magnesia; formerly obtained by evaporating the water of certain springs at Epsom in Surrey. The greater part of the Epsom Salt of commerce is now manufactured from the Magnesian Limestone of Yorkshire, to which the term *Epsomite* has therefore been applied.

Epulis (Gr. *ἐπυλῖς*, a gumboil, from *ἐδλα*, gums). A small tubercle on the gums.

Epulones (Lat.). Priests, appointed first in 196 B.C. to attend to the epulum Jovis, or banquets of Jupiter and the other gods. They formed one of the four great religious corporations at Rome: the other three being the *Augurs*, *Pontifices*, and *Quindecimviri*.

Epulotic (Gr. *ἐπί*, and *ἐδαῖ*, a scar). Applications which promote the skinning over of sores; hence the *epulotic ointments* of old pharmacy.

Equant (Lat. *æquo*, I make equal). In the Ptolemaic Astronomy, this term denotes a circle which was conceived to be described in the

EQUATION

plane of the deferent or eccentric, for regulating and adjusting certain motions of the planets, and reducing them to easier calculation.

Equation (Lat. *equatio*, a making equal). In Mathematics, the name given to the symbolical expression of the equality of two quantities or functions. The equation is said to be an *identical* one when it is satisfied for all possible numerical values of the symbols it contains; the functions equated are then equivalent forms of the same function. In other cases the equation may sometimes be satisfied or rendered identical by giving to one of the symbols x which it contains a particular value. Such a value is called a *root* of the equation, and being usually the object of investigation x is termed the *unknown quantity*. An equation is termed a *numerical* one when, besides the unknown quantity, it contains numerical symbols only; if besides these it contains literal representatives a, b , &c. of known but unstated numbers, the equation is termed a *literal* one. The solution of a literal equation consists of the expression of its root x in terms of the remaining letters. This *general solution* is not always possible in a finite form; on the other hand, the solution of a numerical equation to any required degree of accuracy, can usually be accomplished by certain *methods of approximation*. One of these methods, Newton's, on account of its general applicability, may be here mentioned. If a be an approximate root of the equation $f(x) = 0$, a form to which every equation can obviously be reduced, then a still more approximate root will, in general, be $a - \frac{f(a)}{f'(a)}$, where $f'(a)$ is the first *derived function* of $f(a)$.

An equation is said to be *algebraic* when the operations to which the unknown quantity x is subjected do not transcend the ordinary algebraical operations of addition, subtraction, multiplication, division, involution, and evolution; in other cases the equation is termed *transcendent*, and receives the distinctive names of *exponential*, *logarithmic*, *trigonometrical*, &c., according to the nature of the functions of x which it involves. An algebraic equation is further said to be rational and integral when, in it, the unknown quantity neither appears in the denominator of a fraction nor under any radical sign. It is evident that every algebraic equation can be rendered rational and integral by means of appropriate transformations.

Equation of Differences. An expressed relation between an independent variable x , a dependent variable u_x , and the successive differences Δu_x , $\Delta^2 u_x$ &c. of the latter. These differences are, of course, expressible also by the successive values u_x , u_{x+1} , u_{x+2} , &c. . .

Thus

$$\Delta u_x + 2u_x + x + 1 = 0$$

and

$$u_{x+1} + u_x + x + 1 = 0$$

are equivalent forms of an equation of differences [DIFFERENCES, CALCULUS δ .] Equations

EQUATION, PERSONAL

of differences are classified according to their order and degree in precisely the same manner as differential equations, and there are many points of resemblance in the methods by means of which both are solved.

An *equation of partial differences* involves in general two or more independent variables x, y, \dots , an unknown dependent variable $u_{x,y}$, and one or more of the partial differences or partial successive values of the latter. Thus

$$\Delta_x \Delta_y u_{x,y} + \Delta_x u_{x,y} - u_{x,y} = 0,$$

$$D_x D_y u_{x,y} - D_y u_{x,y} - u_{x,y} = 0,$$

$$u_{x+1,y+1} - u_{x,y+1} - u_{x,y} = 0$$

are equivalent forms of an equation of partial differences of the second order.

The best systematic English treatises on the solution of equations of differences have been already cited. [DIFFERENCES, CALCULUS δ .]

Equations of mixed differences are characterised by the simultaneous presence of differences and differentials. Although noticed in De Morgan's *Differential and Integral Calculus*, in Boole's *Finite Differences*, and in several other works, these equations have been but little investigated.

Equation of Squared Differences. In Algebra, the equation whose roots are the squares of the differences of the roots of a given equation. If the latter is of the n^{th} degree, the degree of the former will be $\frac{n(n-1)}{2}$, for there are so many combinations

of n roots of the form $(a_1 - a_2)^2$, $(a_1 - a_3)^2$ &c. The coefficients of the equation of squared differences can of course be calculated as soon as the sums of the several powers of its roots are known. [SYMMETRIC FUNCTIONS.] The latter, however, are obviously expressible by means of symmetrical functions of the roots of the original equation, in fact by the sums of the powers of its roots, and hence in terms of the known coefficients of this equation. Calling S_1 and S_r respectively, the sums of the r^{th} powers of the roots of the original equation, and of the equation of squared differences, it is found that

$$s_2 = n S_2 - 2r S_1 S_{2r-1} + \frac{2r(2r-1)}{1.2} \\ + (-1)^r \frac{2r(2r-1)}{2r} - \frac{(r+1)}{2r} S_r S_r.$$

The equation of squared differences may be used in separating the real roots of the original [WARING'S METHOD]; it furnishes information, too, with respect to the number of *imaginary* roots of the latter, for it is manifest that the negative as well as the imaginary roots of the equation of squared differences must proceed from imaginary roots of the original, and that the absence of negative roots in the former will necessarily imply the reality of all the roots of the latter.

Equation, Functional. [FUNCTION.]

Equation, Personal. The term *personal equation* has of late been introduced into Astronomy to denote the interval of time by which

EQUATION OF TIME

an observer, on the average of a number of observations, notes a phenomenon before or after the instant assumed to be that of its actual occurrence. If it were possible to determine the true instant of the occurrence of any phenomenon with absolute certainty, the personal equation of an observer would be the amount of error he is in the habit of making, or the probable error of a single observation made by him; but as the true instant of the occurrence can only be assumed by taking the mean of a number of observations, the term has only a relative signification. For instance, if, on comparing a number of observations of the same phenomenon by A and B, it be found that A notes the phenomenon, on the average, half a second sooner than B, then half a second is the *difference* of their personal equations; but this does not enable us to form any judgment with respect to the amount of error due to either, and it is only by a further comparison of observations made by A and B with those of other observers, that we are enabled to assume that the true instant at which the event occurred lies between the times noted by them respectively, or before or after both. If, however, it be assumed that either A or B observes correctly, then the personal equation of the other is half a second.

Generally speaking, the personal equation of an observer is a minute quantity, seldom exceeding a few tenths of a second, but it is sometimes found even in the case of experienced observers to amount to, or even exceed, a whole second. It is found to vary with the age of the observer, and may possibly at all times depend on some measure on the state of his health. See *Introductions to the volumes of the Greenwich Observations*.

Equation of the Centre. The quantity by which the true longitude of the earth differs from the mean longitude.

Equation of Time. In Astronomy, the difference, expressed in mean solar time, between the true or apparent right ascension of the sun and its mean right ascension. It may be somewhat popularly defined as the difference between the times indicated by an accurately constructed sun-dial and a well-regulated clock.

The equation of time arises from the combined operation of all the causes which tend to produce inequalities of the sun's motion in right ascension. The first of these is the eccentricity of the earth's orbit, in consequence of which the sun's motion in longitude is unequal. The second is the obliquity of the ecliptic, in consequence of which the arcs of the ecliptic and equator, counting from the intersection of these circles to the meridian, are in general unequal. A third, but comparatively unimportant, cause arises from the perturbations of the moon and planets.

The equation of time is at its maximum about the beginning of November, when it amounts to about 16 min. 16 sec.; and is subtractive, that is to say, the clock is faster than the dial by

EQUATIONS, THEORY OF

that quantity. At four times in the year the equation vanishes, or the clock time and dial time agree. This happens about the 25th of December, the 16th of April, the 16th of June, and the 1st of September. But these epochs, depending on the longitude of the sun's perigee, are subject to some variation. The equation is given in the *Nautical Almanac* for every day of each year.

Equations, Binomial. [BINOMIAL EQUATIONS.]

Equations, Reciprocal. [RECIPROCAL EQUATIONS.]

Equations, Theory of. Under this name it is customary to include that branch of Algebra in which are investigated the properties of algebraic equations, reduced to the rational and integral form,

$$F(x) = A_0x^a + A_1x^{a-1} + \dots + A_{n-1}x + A_n = 0,$$

where the coefficients $A_0, A_1, \&c.$, denote real quantities. The great problem with the earlier algebraists was the *solution* of such equations, that is to say the discovery of those functions of the coefficients (*roots*) which, when substituted for x , have the property of satisfying the equation by rendering it an identical one. [EQUATION.]

In 1826, however, the Norwegian mathematician Abel (*Œuvres Complètes*) proved that the problem was an impossible one, in finite form, when the degree n of the equation exceeded four. The problem had already been virtually solved for equations of the second, third, and fourth degrees, respectively, by the Hindu algebraists, by the Italian Cardan, and by his pupil Ferrari. [QUADRATIC; CUBIC; BIQUADRATIC; and QUARTIC.] Although our powers are thus limited, however, with respect to the general solution of equations, we are not only in possession of methods by which the roots of numerical equations can be determined to any required degree of accuracy [HORNER'S METHOD], but by the *theory of equations* we can discover numerous properties of these roots. The more important of these properties we propose merely to enunciate.

1. If a be a root of the equation $F(x) = 0$, then the function $F(x)$ is exactly divisible by the binomial $x - a$; and conversely if $x - a$ is a divisor of $F(x)$, a is a root of the equation. When $F(x)$ is divisible by $(x - a)^m$, the equation is said to have m equal roots, a being their common value.

2. Every equation of the n^{th} degree has n real or imaginary roots, and may therefore be written in the form—

$$F(x) = A_0(x - a_1)(x - a_2) \dots (x - a_n) = 0.$$

If, of the roots $a_1, a_2, \&c.$, one should be imaginary or of the form $a + b\sqrt{-1}$, it will necessarily be accompanied by its conjugate $a - b\sqrt{-1}$, and the two will give rise to the real quadratic factor $(x - a)^2 + b^2$.

3. The sum of all the roots of the equation $F(x) = 0$ is equal to $-\frac{A_1}{A_0}$, that of the products

EQUATOR

of every two roots to $\frac{A_2}{A_0}$, &c., generally the sum of the products of every m of the roots is equal to $(-1)^m \frac{A_m}{A_0}$. As a particular case it follows that the product of all the roots must be equal to $(-1)^n \frac{A_n}{A_0}$.

4. Every rational and symmetrical function of the roots of an equation can be expressed in terms of its coefficients. [SYMMETRICAL FUNCTIONS.] In obtaining such expressions, the following easily demonstrated theorem is of great service:

5. If $f(x)$ be any rational and integral function of x , and $F'(x)$ the derived function of $F(x)$, then the coefficient of the highest power of x in the remainder, obtained by dividing $F'(x)f(x)$ by $F(x)$, is $f(a_1) + f(a_2) + \dots + f(a_n)$.

6. There will necessarily be an odd number of real roots between a and β if $F(a)$ and $F(\beta)$ have opposite signs, and an even number (or none) if these functions have the same sign.

7. Between every pair of adjacent real roots of $F(x)=0$ lies a real root of the derived equation $F'(x)=0$.

8. If $F(x)=0$ have m roots (real or imaginary) each equal to a , $m-1$ of them will also be roots of $F'(x)=0$. The equal roots of an equation, therefore, may always be detected and removed. For the latter purpose it is merely necessary to divide $F(x)$ by the greatest common measure of $F(x)$ and $F'(x)$.

9. If f denote the numerical value of the first coefficient in an equation, and g that of the numerically greatest coefficient which has a sign opposite to that of the first, then no positive root can be so great as $1 + \frac{g}{f}$. This theorem suffices at once for the discovery of inferior as well as of superior limits to both positive and negative roots.

With reference to the methods of ascertaining the number of real and imaginary roots between given limits, see STURM'S THEOREM and FOURIER'S THEOREM, of which latter Descartes' useful *rule of signs* is but a particular case. On the theory of equations we have, in English, treatises by Murphy, Young, Hymers, Todhunter and others, and, in French, an excellent work by Serret, *Algèbre Supérieure* (Paris 1849), as well as less recent, but valuable ones by Budan, Lagrange, Fourier and others.

Equator. In Astronomy, the great circle of the celestial sphere, of which the plane is perpendicular to the axis of the earth's diurnal motion. It is called the equator, because when the sun is in its plane the days and nights are exactly equal all over the world. The equator divides the sphere into the northern and southern hemispheres, and the apparent diurnal motions of all the celestial bodies are performed in circles which are parallel to it. The right ascensions are measured on the equator; and the declinations on circles which intersect it at right angles. The equator, in the heavens, is often styled the *equinoctial*.

EQUATORIAL

In Geography, the equator is the great circle of the terrestrial sphere which is everywhere equally distant from the two poles, and divides the earth into the northern and southern hemispheres. Terrestrial *longitudes* are measured on the equator, or some one of its parallel circles; commencing from some arbitrary point, which different nations assume variously, most of them adopting the meridian which passes through their capital city or principal observatory. *Latitudes* are counted from the equator along the meridian.

Equatorial. An astronomical telescope, mounted for the purpose of continuously observing and noting the right ascension and declination of a celestial body situated in any part of the visible heavens, as opposed to the *transit-instrument*, which is used only in the meridian of the place, and to the *altitude* and *azimuth* instrument, which measures those coordinates from which its name is derived. The principal axis of the equatorial mounting is parallel to the earth's axis, and by means of this construction it is possible to follow a star from rising and setting by driving the telescope, either by hand or machinery, westward, at the same rate at which the earth's motion carries it eastward. On the polar axis there is fixed a graduated circle, the plane of which is perpendicular to the polar axis, and therefore parallel to the earth's equator. This is called the *hour circle*, and is furnished with two indices. If one be set to sidereal time at the place of observation, which of course represents the right ascension of the part of the heavens then crossing the meridian, the other index will show the right ascension of the part of the heavens to which the telescope points. In this manner the right ascension of a comet, for instance, may be at once found, or the telescope may be pointed to any given right ascension. But the telescope itself is attached to another axis, called the *declination axis*, at right angles to the former one; and to this axis is also attached at right angles another circle, the *declination circle*. The plane of the second circle and of the telescope's motion in declination is thus in all positions at right angles to the plane of the first or equatorial circle. Now it is easy to conceive, from this general description, that when the telescope is pointed to a star, the angle between the direction of the telescope and the polar axis is equal to the polar distance of the star; and by setting the index of the declination circle to zero when the telescope is at right angles to the polar axis, the declination of a star is registered in all positions of the instrument; consequently, when a motion is given to the polar axis without altering the position of the telescope on the declination circle, the point to which the telescope is directed will always lie in the small circle of the heavens coincident with a star's diurnal path; and hence, if the motion communicated to the polar axis be equal to the earth's diurnal rotation, a star will remain constantly in the field. The best equatorials are now furnished with *driving clocks*. Besides relieving the observer from the fatigue of turning

EQUATORIAL CURRENT

the instrument, the motion thus given is perfectly equable, and all those jerks are avoided which, when the instrument is turned by the hand, often prove fatal to an observation. [TELESCOPE.]

Equatorial Current. An important part of the stream currents of the Atlantic, first distinctly traceable off the coast of Africa, a little south of the equator, whence it continues to run, nearly on the line, for a distance of 1,000 miles as far as 22° west longitude. It then sends off a branch to the north-west, and declining southwards runs for some distance parallel to the coast of South America until it is lost sight of near the mouth of the Amazona. Including both branches, it has a course of about 4,000 miles. Its breadth, at first only 150 miles, becomes three times as great where it branches near the South American coast. It has a mean velocity of 36 miles per day, but at certain seasons and in some part of its course it has been recorded as reaching more than three and a half miles an hour. It is generally throughout its course a cold current, but the difference is not more than four or five degrees when compared with the mean temperature of the ocean in any given latitude.

The northern portion of this great current passes along the coast of Guiana and enters the Caribbean Sea, where it is ultimately lost, or perhaps is converted into warm water, and then is passed out through the gulf of Mexico into the Atlantic to assist in forming the GULF STREAM.

Esquerry (Fr. *écuyer*). In the British court, a subordinate officer under the master of the horse. The chief esquerry is also styled *clerk marshal*, with a salary of 500*l.* per annum. There are also four esquerries in ordinary, whose salary is 300*l.* a year, and an esquerry of the crown stable. A queen consort has three esquerries.

Equiangular. In Geometry, two or more figures of the same kind (usually rectilinear) are said to be equiangular when the angles of the one, taken consecutively, are respectively equal to the angles of the other. A single figure is also said to be equiangular when all its angles have the same magnitude.

Equiangular Spiral. A name sometimes given to the logarithmic spiral in consequence of its having the property of cutting, at the same angle, all its polar radii vectores. [LOGARITHMIC SPIRAL.]

Equilateral (Lat. *æquilateralis*, from *latus*, a side). In Geometry, a rectilinear figure is said to be equilateral when all its sides are equal. If, moreover, its angles are all equal, it is called *regular*. Every equilateral figure inscribed in a circle is necessarily equiangular, and therefore regular. The converse theorem, however, is only true for polygons with an odd number of sides. Equiangular inscribed polygons with an even number of sides, if not equilateral, will at least have every alternate side equal.

Equilateral Bivalve. A shell is so called when a transverse line drawn through the apex

EQUINOCTIAL POINTS

of the umbo bisects the valve into two equal and symmetrical parts.

Equilateral Hyperbola (Gr. *ὑπερβολή*). An hyperbola whose axes are equal. Its asymptotes being perpendicular to each other, it is sometimes called also a *rectangular hyperbola*. Every equilateral hyperbola cuts the line at infinity in two points which are harmonic conjugates with respect to the imaginary circular points in that line, and conversely every conic which so cuts the line at infinity is necessarily a rectangular hyperbola. From this may be deduced the interesting property that every conic which passes through the intersection points of two equilateral hyperbolas is itself an equilateral hyperbola.

Equilateral Hyperbolic Paraboloid. A quadric conoidal surface generated by a right line which, during its motion, rests upon two other right lines or *directrices*, to one of which it always remains perpendicular. [QUADRIC.]

Equilibrium (Lat. *æquilibrium*, from *libra*, balance). The state of rest produced by two or more mutually counteracting forces. [COMPOSITION AND RESOLUTION OF FORCES.]

EQUILIBRIUM. In the Fine Arts, the just place or balance of a figure, or other object, so that it may appear to stand firmly. Also the due equipoise of objects, lights, shadows, &c., against each other by some striking features. This quality is obvious in the works of nature, as well in the human form as in landscape. In the latter, for instance, the sun is generally the medium of producing it by strong contrasts of light and shadow. In Architecture, the same means are employed to produce the most striking effects.

EQUILIBRIUM. In Politics. [BALANCE OF POWER.]

Equilibrium Surface. In the theory of attraction, one which is everywhere normal to the resultant of attraction upon any material particle placed thereon. Its equation is obtained by putting the potential equal to a constant. The equilibrium surface is the orthogonal trajectory of the *lines of force*. [POTENTIAL.]

Equipomental Cone and Surface. INERTIA, MOMENT OF.]

Equipomultiples. Two or more magnitudes, alike or unlike in kind, are said to be equipomultiples of as many other like magnitudes, when each magnitude of the first set contains the corresponding magnitude of the second set the same number of times. Thus *m*A and *m*B are equipomultiples of A and B, whatever magnitudes the latter may represent.

Equinoctial. [EQUATOR; EQUINOX.]

Equinoctial Time. Astronomers sometimes give the date of an occurrence in equinoctial time to get rid of local differences. This is reckoned from the moment when the point of Aries passes the vernal equinox.

Equinoctial Points. The two opposite points of the celestial sphere, in which the ecliptic and equator intersect each other; the one being the first point of Aries, and the other

EQUINOX

the first point of Libra. The equinoctial points do not retain a fixed position relatively to the stars, but retrograde or move backwards from east to west with a slow motion, equal to about 50 seconds yearly, requiring 25,000 years to accomplish a complete revolution. This motion is called the *Precession of the Equinoxes* [which see].

Equinox (Lat. *æquus*, *equal*, and *nox*, *night*).

In Astronomy, the time at which the sun passes through the equator in one of the equinoctial points. When the sun is in the equator, the days and nights are of equal length all over the world, whence the derivation of the term. This happens twice every year; namely, about the 21st of March and the 22nd of September: the former is called the *vernal* and the latter the *autumnal* equinox. The equinoxes do not divide the year into portions of equal length; for in consequence of the earth being at its greatest distance from the sun during the summer months, and its angular motion in its orbit being consequently slower, the interval from the vernal to the autumnal equinox is greater than that from the autumnal to the vernal. In other words, the sun continues longer on the northern than on the southern side of the equator. At the beginning of the present century, the difference amounted to 7 days 16 hours and 51 minutes. The summer in the northern hemisphere is consequently longer than in the southern by this quantity; and to this circumstance some meteorologists ascribe, in part at least, the higher temperature that is found to prevail in the northern hemisphere under the same parallel. — [PRECESSION.]

Equipage (Fr.). In ordinary language, signifies the carriage, horses, and liveries which indicate the fortune or rank of any gentleman when he appears abroad.—*Equipage*, in marine affairs, signifies the crew of a ship, together with all a ship's furniture, masts, sails, ammunition, &c.—In military language, *Camp equipage* means the tents and appliances necessary for encampment.

Equipollence (Lat. *æquipolles*). In Logic, when two or more propositions signify one and the same thing, though they express it differently.

Equipollence, Calculus of. In Mathematics, a symbolical calculus, invented by Professor Bellavitis of Padua. In many respects it is analogous to the barycentric calculus of Möbius, the double algebra of De Morgan, and the calculus of quaternions of Sir W. R. Hamilton. (*Memorie dell' Istituto Veneto di Scienze*, vol. viii. 1860.)

Equipotential Surface. [POTENTIAL.]

Equiria (Lat. from *equus*). Roman horse-racing games, said to have been instituted by Romulus in honour of Mars; they were celebrated twice every year in the Campus Martius.

Equisetaceæ (Equisetum, one of the genera). In Botany, a natural order of Cryptogams, inhabiting the ditches and rivers of most parts of the world. They have no decided affinity with any known order, but bear an external resemblance to such Gymnosperms as *Ephedra*,

EQUITY

and in their fructification to the order of *Cycas*. They have no medicinal qualities; but for economical purposes are useful for polishing furniture, owing to the quantity of silice contained in their epidermis. For this latter purpose, large quantities of *Equisetum hyemale* are imported under the name of Dutch Rushes. They are considered by the farmer, who calls them Horse-tails, as a sign of heavy, bad, wetland.

Equisetie Acid. A peculiar acid, discovered by Braconnot, existing, combined with magnesia, in the *Equisetum fluviatile*.

Equitangential Curve. One whose tangents are all intersected by a given line at the same distance from the respective points at contact. [TRACTRIX.]

Equitant (Lat. *equitare*, to ride). In Botany, a term used in describing the venation of leaves, to denote that they overlap each other entirely and without any involution, as the leaves of the iris.

Equites (Lat. *horsemen*). In Ancient History, a class of Roman citizens, commonly represented by the English word *knight*, but not answering in all respects to its meaning. According to the account of Livy (i. 13), Romulus constituted three centuries of equites, to whom he gave severally the names Ramnenses, Titienses, and Luceres. Livy, however, elsewhere speaks of these three centuries (who were collectively called *Celeres*) as the three ancient tribes. (Sir G. O. Lewis, *Credibility of Early Roman History*, i. 438 &c.) Down to the time of Gracchus, the equites formed simply a division of the army, and their centuries were composed of patricians and plebeians; but by the Lex Sempronia, B.C. 123, a new class called the *Ordo Equestris* was instituted, and all the judices, who assisted the prætor in trials, were to be citizens of equestrian fortune. The reform of Sulla deprived the equites of the sole right of being chosen as judices, and the latter were now to be chosen from the senators, equites, and tribuni ærarii. The badges of the equites were a golden ring and a robe with a narrow purple border; and to them were appropriated the fourteen rows of seats in the theatres next the orchestra. The equites furnished the farmers of the public revenue, or publicani; but though they had enjoyed this privilege under the republic, it was only during the empire that they looked to such offices as their birthright. Cicero affirms that the flower of the Roman chivalry, the ornament of Rome, the strength of the empire, lay in these farmers of the public revenue: 'Florem equitum Romanorum, ornamentum civitatis, firmamentum reipublice, publicanorum ordine contineri.'

Equity (Lat. *æquitas*). In Jurisprudence. In the words of Blackstone (*Commentary* i. 61), 'Since in laws all cases cannot be foreseen or expressed, it is necessary that when the general decrees of the law come to be applied to particular cases, there should be somewhere a power vested of defining those circumstances which (had they been foreseen) the legislator himself would have expressed.' In the ----

view, Grotius defines equity as 'Correctrix ejus in quo lex propter universalitatem deficit' (*De Aequitat.* l. a. 12); and distinguishes it from the dispensing power, which does not mitigate law, but dispenses certain persons from the obligation of it. Puffendorf considers it under two heads—as declaring a case to be excepted out of the general provisions of a law; and as deciding omitted cases on which the law does not pronounce at all. (*Elements*, i. 22, 23.) The necessity of some power to modify and apply, with allowances for particular cases, the strict rules of law, is necessarily felt in every jurisprudence, and provided for in different ways. Thus in ancient Rome the prætor, 'juvare, supplere, interpretari, mitigare, jus civile potuit; mutare vel tollere non potuit.' (*Digest*, l. i. t. l. 7.) So, in English law, the judges have constantly assumed the authority to pronounce cases to be within the equity, as it is termed, of statutes or rules, when they are not within its words; as, for example, action of waste given by the Statute of Gloucester against tenant for life 'or years' is extended by equitable construction against tenants who hold for a year or half a year only. But the word equity, in English jurisprudence, is now more properly applied to a separate body of law, created and sustained on the strength of precedents, and administered by tribunals distinct from the common law courts of the country. The separation of equity from law originated in the necessity which has already been spoken of; but from the circumstance of the former being administered by a different class of functionaries, it has by degrees assumed this distinct shape and substance. By seeking relief in equity is now meant, not so much applying for a mitigation of the strict rules of law, as seeking a remedy before a tribunal having a jurisdiction either concurrent with the courts of law or (in some cases) exclusive, but exercising it according to a different process and on different principles. The origin of this peculiar system is to be traced, in part, to the system of uses [Use; Trust]; in part to the obvious advantages resulting from the examination of the parties, and compelling discovery on oath in cases of fraud, account, &c.; and to the power, gradually acquired by equity judges, of compelling the specific performance of contracts where courts of law could only award damages for their breach; in part, also, to the peculiar functions imposed by statute and usage on the lord chancellor as guardian of infants, idiots, and lunatics, superintendent of charities, &c. The general view of the system of equitable jurisprudence as at present existing is given in the article Trust. (*Blackstone's Commentaries*, vol. iii.; *Fonblanque On Equity*; *Story's Equity Jurisprudence*; *Spence On Equitable Jurisdiction*, vol. i.)

Equity of Redemption. In Law. [MORTGAGE.]

Equivalents, Chemical. A term introduced into Chemistry by Dr. Wollaston to express the system of definite ratios in which

substances reciprocally combine, referred to a common standard of unity. If we assume hydrogen as unity, it being the substance which combines with others in the smallest relative weight or proportion, then all other substances may be represented by certain multiples of that unit, expressed with sufficient precision for ordinary purposes by whole numbers. [ATOMIC THEORY; AFFINITY.] Thus, upon this system the equivalent number of oxygen will be 8, and that of water will be 9, for 8 oxygen + 1 hydrogen = 9 water; the equivalent of potassium will be 39 and of potassa or oxide of potassium 47, for 39 potassium + 8 oxygen = 47 potassa. Upon the same principle the equivalent of hydrochloric acid, which is a compound of chlorine and hydrogen, is 37, for it consists of 1 part by weight of hydrogen and 36 of chlorine; or, in other words, of an atom of hydrogen = 1 + an atom of chlorine = 36. The equivalent of sulphur is 16; to form sulphuric acid one atom of sulphur = 16 combines with 3 atoms of oxygen (8 × 3) = 24; hence the equivalent of an atom of sulphuric acid is 16 + 24 = 40. These equivalents are often expressed by certain abbreviations, termed *chemical symbols*, which, as far as single equivalents of the simple substances are concerned, are represented, together with their equivalent numbers, in a table in the article CHEMISTRY.

Equivalent. A bivalve is so called when its two valves are of similar size and form.

Equivoocal Term (Lat. *equivocus, ambiguus*). In Logic, a term which has several significations, applying respectively and equally to several objects. A word is generally said to be employed equivocally where the middle term is used in different senses in the two premisses [SYLLOGISM]; or where a proposition is liable to be understood in various senses, according to the various meanings of one of its terms.

Equuleus (Lat.). Called also *Equulus* and *Equus Minor*. The *Little Horse*; one of Ptolemy's constellations in the northern hemisphere.

Equulus. In Roman Antiquities, the name given to a species of rack used in extorting confessions.

Equus (Lat. *a horse*). The generic name of the quadrupeds with a single digit and hoof on each foot, as the *horse, ass, and zebra*. Of these species the horse is the largest, most docile, most valuable, and most widely distributed over the globe. Of the Mammalia which existed on the earth's surface during the tertiary periods of geology, the horse is one of the few which have been preserved to the present epoch; and in the American continent, where it once became extinct, along with the Mastodon and Megatherium, it now again ranges wild in vast troops, the descendants of the war-horse introduced by the European discoverers and conquerors of the so-called New World.

The wild horses which inhabit the steppes of Tartary are supposed to be, like those that traverse the pampas of South America, the descendants of certain individuals which have

escaped from the thralldom of man. The best of the wild Asiatic races are those which inhabit Tscherkessi Abassi, and the northern slopes of the Caucasian range. The principal varieties which Pallas indicates in the Asiatic horse are: the *mustachoid horse*, characterised by numerous strong bristles on the upper lip; the *woolly horse*, a Russian variety, covered with a crisp woolly hair, and common among the Baschkirs; a *hairless* or naked horse, not uncommon amongst the Krim Tartars, who keep it always clothed; and lastly, the variety delineated by Johnston, in which a woolly mane is continued from the neck along the middle of the back to the tail, and which Pallas saw among the Burati.

The wild horses appear to be free from nearly all those diseases to which the domestic breed are prone. They are generally of a pale or greyish-brown colour, with brown mane and tail, a whitish muzzle, changing to black about the mouth. They are less than the domestic breed; with a larger head; longer legs; larger ears, with the apices sub-reflected; the forehead is more convex above the eyes; the hoofs are contracted and subcylindrical (*ungula contracta, subcylindracea*); mane sub-erect, less lax than in the domestic horse; the coat, in winter, looser and subundulating along the back (*in dorso subundulatum*); the tail not very large. They recognise the presence of man at a great distance when he approaches them to windward, and fly from him with wonderful speed; they prefer sunny slopes, and avoid forests and steep places. They do not wander beyond the 50th degree of north latitude.

The first change which domestication works upon the form of the wild horse is to increase the bulk of his trunk as compared with his head and limbs. This change is beautifully exemplified in the Arabian, which we must regard as an early, if not first, remove from his wild neighbours of the more northern deserts, which the Bedouin still hunts for the sake of their flesh. The head is not only proportionally smaller, but is remarkable for the breadth and squareness of the forehead, the shortness and fineness of the muzzle, the prominence and brilliance of the eye, and the smallness of the ears. The body is still somewhat light, and narrow at the forepart; but the shoulder is superior in its formation to that in any other breed. The Arabian seldom stands more than fourteen hands two inches. The Barb, so called from its native country, Barbary, is somewhat smaller than its near ally the Arabian; it seldom exceeds fourteen hands and an inch; the shoulders are flat, the chest round, the legs rather long, and the head small and very beautiful. The Barb is remarkable for its fine and graceful action; but though it is superior to the Arabian in its general form, it has not its untiring spirit or its speed. Our most valuable English varieties of the horse date from the introduction of, and interbreeding with, the Barb and Arabian.

We have no means of ascertaining the nature

or peculiarities of the horses which the ancient British charioteers managed with such dexterity in their destructive charges through the disciplined troops of Caesar. They must have been subsequently modified by crossing with the Roman horses. King Athelstan received from Hugh Capet of France several German running horses; William the Conqueror and his followers introduced the Spanish horse, with the blood of the Barb. The first Arabian horse is recorded to have been introduced in the reign of Henry I.; and a greater admixture of Arabian blood was a natural consequence of the return of the Crusaders. King John devoted especial attention to the improvement of his stud; and he imported one hundred choice stallions of the Flanders kind. The size and strength required to carry the warrior clad in the heavy armour of those days led to the frequent introduction in subsequent reigns of the large and heavy war-horses of the Low Countries. Afterwards, when the nobles derived their amusements more from the sports of the turf and field, they were induced to cross their stately and heavy breed of war-horses with those of lighter structure and greater speed; the latest improvement seems to have been derived from a direct intermixture of the pure Arabian.

The principal varieties of breeds of English horses are: The hackney or road horse. 'Ho should be,' Mr. Youatt observes, 'a hunter in miniature; with these exceptions: His height should rarely exceed fifteen hands and an inch. He will be sufficiently strong and more pleasant for general work below that standard. He should be of a more compact form than the hunter, of more bulk according to his height. It is of essential consequence that the bones beneath the knee should be deep and flat, and the tendon not tied in. The pastern should be short, i

ng than that of foot should be of a size corresponding with the bulk of the animal, neither too hollow nor too flat, and open at the heels. The forelegs should be perfectly straight; for a horse with his knees bent will from a slight cause, and especially if over-weighted, come down. The back should be straight and short, yet sufficiently long to leave comfortable room for the saddle between the shoulders and the huck without pressing on either. Some persons prefer a hollow-backed It is generally an easy one to go. It will canter well with a lady; but it will not carry a heavy weight or stand much hard work. The road horse should be high in the forehead, round in the barrel, and deep in the chest.'

The origin of the better kind of coach horse, says Mr. Youatt, is the *Cleveland bay*, confined principally to Yorkshire and Durham, with Lincolnshire on one side and Northumberland on the other, but difficult to meet with pure in either county. The Cleveland mare is crossed by a three-fourth or thorough-bred horse of sufficient substance and height, and the produce is the coach horse most in repute, with his arched crest and high action.

EQUUS

There is, or rather was, a breed called, from its round punchy make, the *Suffolk punch*. 'It stood from fifteen to sixteen hands, of a sorrel colour; was large-headed, low-shouldered, and thick on the top; deep and round-chested; long-backed; high in the croup; large and strong in the quarters; full in the flanks; round in the legs, and short in the pasterns. It was the very horse to throw his whole weight into a collar, with sufficient activity to do it effectually, and hardihood to stand a long day's work.' This valuable breed is now nearly extinct: it is thought to have been produced from the Norman stallion and the Suffolk cart mare. Excellent carriage horses are obtained by crossing the Suffolk breed with a good hunter.

The best dray horses are produced from the Suffolk punch crossed with the Flanders.

The breed of English racers is traced authentically to an Arabian stallion introduced into this country by a Mr. Darley, and hence called the *Darley Arabian*. Anterior to this period the pedigree of a racer can rarely be carried back beyond some obscure reference to an Eastern horse. The Darley Arabian was the sire of Flying Childers, and the great-grand sire of Eclipse. Eclipse was remarkable for the very great size, obliquity, and lowness of his shoulders; the shortness of his forequarters; his ample and finely proportioned quarters, and the swelling muscles of his fore-arm and thigh. He was, moreover, what is termed a *thick-winded* horse, and puffed and roared so as to be heard at a considerable distance; yet he never had an opponent on the turf sufficiently fleet to put his full speed to the test. Eclipse died at the age of twenty-five years, having begot the extraordinary number of three hundred and thirty-four winners. Another stream of Eastern blood was introduced into the swelling veins of our thorough-bred horses by a beautiful Barb, called the *Godolphin Arabian*.

The hunter, a favourite English variety, includes as much of the blood and high breeding of the racer as is compatible with the power and endurance demanded by the chase. The author of the excellent work on the horse in the *Library of Useful Knowledge* thus describes the good points of a hunter: 'The first property of a good hunter is, that he should be light in hand. For this purpose his head must be small; his neck thin, especially beneath; his crest firm and arched; and his jaws wide. The head will then be well set on. It will form a pleasant angle with the neck, which gives a light and pleasant mouth.'

The more extreme varieties which we have in England are the ponies and Galloways: of these the Sheltie or Shetland pony is the most diminutive; it rarely exceeds nine hands high, and sometimes does not reach seven and a half. His strength is proportionally far greater than his size; he is perfectly docile, and will fatten on the hardest fare.

The dental character of the horse, and of the genus *Equus*, is thus expressed in zoology:—

incisors $\frac{1-1}{6}$, canines $\frac{1-1}{1-1}$, molars $\frac{6-6}{6-6} = 40$;

i. e. it has six incisors or nippers in the front of both the upper and lower jaws, one tusk or canine, and six molars or grinders, on each side of both jaws. They appear in the following order. The two middle incisors and the two anterior grinders come into place at about a week after birth; the third grinder in the course of the first month; the two adjoining incisors before the end of the sixth week; the two outer incisors between the sixth and ninth month; making the six incisors above and below, and completing what is termed the *colt's mouth*. There are also two very small deciduous canines developed about the sixth month; the fourth grinder generally makes its appearance at the end of the first year, and thus the formula, incisors $\frac{6}{6}$, molars $\frac{4-4}{4-4}$,

is characteristic of the yearling foal. A fifth grinder makes its appearance at the end of the second year; and now commences the displacement of the first set, and the protrusion of the second or permanent set of teeth. The deciduous teeth are lost in the order of their acquisition; the two middle incisors of both the upper and lower jaws are displaced *between the second and third years*; the first and second deciduous grinders are shed at two years and eight months. A *three-year old* colt has the permanent middle incisors above the gum, but not on a level with the adjoining deciduous incisors; they are also characterised by a large and deep groove containing a black substance traversing transversely the working edge of the crown of the tooth; the *sixth grinder is also coming into place. At three years and a half or little later the adjoining deciduous incisors are shed, and their large successors begin to peep above the gum; the small lateral incisors are diminished in size and much worn. This gives a very characteristic condition to the mouth.*

At four years the sixth grinder has attained the level of the others; the permanent tusks begin to appear; the second permanent incisors have come into place, and are marked with a deep fissure extending quite across the edge of the crown; the corresponding mark in the middle incisors is worn wider and fainter; the third deciduous grinder is shed. The external incisors are shed between four and a half and five years. At five years their permanent successors are in place, with a long deep mark on the inner side of the edge of the crown. The corresponding mark is much worn in the middle incisors, and to a less degree in the adjoining ones. The tusks are about an inch in length. At six years the mark or fissure on the middle incisors is worn away, but a discolouration on the part remains; the mark in the adjoining incisors is shorter, broader, and fainter; and the lateral incisors present the edges of the enamel in a more regular state, and evidently worn; the tusks are an inch in length and pointed; the third permanent grinder has taken its place in the dental series. At seven years

the mark is worn away on the four middle incisors in both jaws, and is in progress of obliteration in the lateral incisor; the apex of the canine or tusk is blunted. At *eight years* the mark is gone from all the lower incisors, and they cease to afford any indication of the subsequent age of the horse. The tusks are rounded off; the marks remain longer on the incisors of the upper jaw. Of course the marks are obliterated in proportion to the friction to which the teeth are subject; they are sooner lost in a stall-fed horse than in one at grass; they are prematurely worn away in the crib-biter.

The age of a horse being always calculated from the first of May, it is very difficult to determine whether the animal be a late foal of one year or an early one of the next. A horse may be made to appear older than he really is by premature extraction of the deciduous teeth: or younger by imitating artificially the natural marks of the incisors after they have been obliterated by attrition; but these frauds are readily detected when all the concomitant conditions of a horse's mouth are scanned by the practised eye.

Owing to the premature labour to which the horse is in general condemned in this country, and to the present rapid rate of travelling, he has rarely a chance of living out his natural term of existence. A well-used horse may last between thirty and forty years. Mr. Percival gives an account of a barge-horse that died in his sixty-second year. Mr. Youatt quotes the record of another horse that received a ball in his neck at the battle of Preston in 1716, and which was extracted at his death in 1768.

Era. [*Æra*.]

Eradicated (Lat.). In Heraldry, an epithet for a tree or flower torn up by the root.

Erased (Lat. *erassus*, part. of *erado*, *Iscrapo* off). In Heraldry, signifies anything forcibly torn off, leaving the edges jagged and uneven; as, a lion's head erased, &c.

Erastians. The followers of Erastus, a German divine, born 1624; a sect which obtained some notoriety in England in the time of the civil wars. They referred the punishment of all offences, civil or religious, to the civil magistrate; and asserted that the church had no power to enforce any acts of discipline, nor to refuse the communion of the Lord's Supper to anyone who desired it.

Erato (Gr.). In Mythology, the muse who presided over love poetry. (Hesiod. *Theog.* 78.)

Erbium. A metal, the oxide of which, *erbia*, is stated by Mosander to accompany yttria, but its presence has not been satisfactorily ascertained.

Erebus (Gr. *Ἔρεβος*). In Greek Mythology, the son of Chaos and Darkness, who dwelt in the gloomy space through which the souls passed to Hades.

In Heraldry, any animal or part of an animal which, being naturally horizontal, is placed perpendicularly.

erasis (a word made up of Gr. *ἔρεβος*, gently, and *ναῖος*, a burning). A retrogressive

change brought about in dead animal and vegetable matter by the chemical action of the oxygen of the atmosphere. The process is precisely the same as occurs when fuel is burnt in an ordinary fire-grate; the rapidity of the operation in the latter case, however, causes such a sensible appreciation of the evolved heat and resulting light as to necessitate another word to express the phenomena, viz. *combustion*. The term *decay* has a wider and looser application than that of *eremacausis*. It is used to indicate natural disintegration of any kind. Thus old walls are said to *decay*, not from any absorption of oxygen, but chiefly from the *mechanical* action of rain and frost, whilst old dead trees in decaying literally burn slowly away.

Erethismus (Gr. *ἐρεθίζω*, to excite or irritate). A state of great general over-excitement induced by abuse of mercury, or depressing agents. It shows a small feeble and quick pulse, precordial sinkings, faintings, &c., and occasionally terminates suddenly in death. The tongue may be clear throughout the disease, and the secretions natural.

Ergastulum (Lat. from Gr. *ἐργαστήριον*, *work*). A workhouse, or a dwelling place for the slaves; they are described by the old Roman authors upon agriculture as dark unventilated rooms, where all kinds of cruelty were practised on the unfortunate victims.

Ergot (Fr. *a sparg*). A disease of the seed of rye and other grasses, produced by the attacks of fungus, *Ergot* possesses of the ovary, destroys it, producing in its room a long, black, hard, hornlike body. Ergot is remarkable for its specific stimulating effects upon the uterus, and is much employed in cases of difficult parturition. Hence it received the name of *Oidium abortifaciens*. It causes dangerous gangrene when taken, as it sometimes has been, among bread-corn; and as it is in some seasons extremely abundant, there can be no doubt that to it may be attributed much of the injury sustained by flocks and herds, either in the shape of gangrene, or by causing them to slip their young. [*Excootism*.]

Ergotin. The acrid bitter active principle of ergot.

Ergotism. The condition produced in those who partake of ergotised or diseased rye as an article of food. The symptoms occurring from ingestion of this poison in small and continuous doses are of very marked character. The disease has been called by various names. We have adopted the French name, while the Germans call the disease the *Kriebelkrankheit* or creeping sickness. Nearly every part of the Continent has suffered at some time or other from ergotism, appearing as an epidemic. It attacks persons of both sexes and of all ages. The disease is divided into two forms, viz. *convulsive* and

gang
ma first is characterised by marked head symptoms, such as vertigo, weariness, partial loss of sight and of sensibility, formication, contraction of the muscles of the extremities, and

ERICACEÆ

partial jaundice. In the early stage the appetite is voracious; but the severer symptoms soon supervene, and death occurs by convulsion. In the gangrenous form the appetite is voracious, and the sense of formication is also observed as in the convulsive form of the disease. The extremities then become colder than in their natural state, and gangrene sets in. Ergotism was probably known long before the cause was detected, for we find the following curious passage in the works of Sigebert about the year 1089: 'A pestilent year, especially in the western parts of Lorraine, where many persons became putrid in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten, and became black like coal. They either perished miserably, or, deprived of their putrid hands and feet, were reserved for a more miserable life.' Ergotised rye is used medicinally in several forms of disease, but more especially to increase the expulsive efforts of the womb in protracted labours, and to restrain uterine hæmorrhage. In cases of poisoning by a large dose of ergot, the symptoms are nausea, dryness of throat, pain in the abdomen, stupor and dilated pupil. In pregnant females abortion occurs.

Ericaceæ (Erica, one of the genera).

natural order of shrubby hypogynous Exogens, inhabiting the Cape of Good Hope and many other places. It differs from *Vacciniacæ* and *Campanulacæ* in the superior ovary; from *Epacridacæ* in the anther being two-celled; from *Pyrolacæ* and *Monotropacæ* in the structure of the seeds, and in habit; and from all the orders represented by *Scrophulariacæ* and *Gentianacæ* in the number of the cells of the ovary agreeing with the lobes of the calyx and corolla. Their general qualities are astringent and diuretic, some few being poisonous. The *Arbutus*, *Andromeda*, *Kalmia*, *Rhododendron*, *Asalea*, all well-known shrubby plants of great beauty, belong to this order.

Erichthians. [ERICHTHUS.]

Erichthus. A genus of long-tailed Decapod Crustaceans, inhabiting the tropical ocean. These crustaceans are remarkable for the delicate and often transparent and colourless character of their large and undivided thoracic shield or carapace, which is always terminated anteriorly in a styliform rostrum: they have no movable rostral plate, and the gills are in general very small and simple, and sometimes wholly inconspicuous. The genus thus characterised is now subdivided into *Squillierichthus*, *Almia*, and *Erichthus* proper; and the whole are included under the family name of *Erichthians*, or *Erichthideæ*, which in the natural system ranks next to the *Squillidæ*, or sea mantises.

Eridasus (Lat.). In Astronomy, one of the ancient constellations in the southern hemisphere, first mentioned by Aratus.

Erinaceus (Lat. a *hedgehog*). A genus of useful insectivorous Mammals, of which our common hedgehog is a well-known and undeservedly persecuted species. The teeth are

ERIOBOTRYA

small, and form a series of sharp bristling points, well adapted for the crushing of beetles, or cracking the backbone of a snake; but quite inadequate to the purpose of self-defence against larger carnivorous quadrupeds. Nature has, however, provided the hedgehog with a coat of armour, thickly bristled over with strong elastic spines, and capable of being drawn by powerful cutaneous muscles over every part of the body. When the hedgehog thus puts himself in a defensive attitude, he resembles a bristled sphere; and is capable of enduring hard blows or heavy falls without suffering material injury.

As the food of the hedgehog consists almost wholly of cold-blooded animals, which in our climate almost entirely disappear from the scene of nature in the winter season, the hedgehog must have starved if he had not been endowed with the singular property of subsiding into a state of suspended animation during the period of famine. In order, however, to preserve the low temperature which he then possesses, he prepares in some retired hole a soft nest of moss and leaves; and thus passes his winter. All the store of nutriment which he carries with him to his place of hibernation is a thick layer of fat about his viscera and beneath his skin, which is slowly absorbed, as the little waste of his inactive life requires, and more rapidly during the first few days of his resuscitation in spring. The female produces from two to four young ones in the summer; they are blind, and covered with soft and flexible spines. The hedgehog has thirty-six teeth. The intermaxillary bones contain six teeth, of which the two anterior are longer than the rest, placed wide apart, directed obliquely downwards with a slight convergence. The six upper incisors are opposed to six below, of which the two anterior ones have the same disproportionate size as the corresponding ones above. Of the remaining teeth, the four posterior ones on each side of both jaws are large, multicuspidate, true molars. The intermediate teeth are small, with two fangs, and represent the spurious molars.

Erinyes, less correctly **Erinnyes** (Gr. *spurts*). In the mythology of Æschylus, the Erinyes are invisible beings who execute judgment on those who have shed blood. Thus the Erinyes of Clytemnestra haunt Orestes, until he is delivered from them by the verdict of the Athenian Areopagus. But these personal attributes do not belong to them in the Vedic mythology, where Eriny appears under the name *Saranyâ*, as the fresh and early dawn. The transition is easily explained. The original phrase applied to the guilty was, '*Saranyâ* [the light] will find out your sin;' and as soon as Eriny became a person, she would naturally be invested in sombre and gloomy colours.

Eriobotrya (Gr. *Ipur*, wool, and *Bêrpus*, bunch). The Loquat or Japanese Medlar, *E. japonica*, is the principal plant of this genus of *Pomacæ*. It is an evergreen, with terminal spikes of flowers succeeded by oval pale orange

fruit of the size of a small apple, and having sharp subacid flavour. It blossoms too early to be grown as a fruit outdoors in this country, and is hardly worth house culture; but in warmer countries, as at Malta, it succeeds admirably. It is cultivated in many parts of India, as well as in China and Japan. In warm countries its subacid fruit is grateful to the palate.

Eriocaulaceæ (Eriocaulon, one of the genera). A natural order of Endogens, of the Glumal alliance, inhabiting the marshes or moist parts of the world: usually combined with *Restiaceæ*. It is composed of herbaceous plants, with cellular spongy leaves, and flowers growing in close heads; it contains no species of any known use. Some of the *Eriocaulons* of Brazil grow six feet high.

Eriometer (Gr. *ἔριον*, wool, and *μέτρον*, measure). An optical instrument for measuring the diameters of minute particles and fibres, by ascertaining the diameter of any one of the series of coloured rings which they produce. 'The eriometer is formed of a piece of card or a plate of brass, having an aperture of about a fiftieth of an inch in diameter in the centre of a circle about half an inch in diameter, and perforated with about eight small holes. The fibres or particles to be measured are fixed in a slider; and the eriometer being placed before a strong light, and the eye assisted by a lens applied behind the small hole, the rings of colours will be seen. The slider must then be drawn out or pushed in till the limit of the first red and green ring (the one selected by Dr. Young) coincides with the circle of perforations, and the index will then show on the scale the size of the particles or fibres.' (Brewster's *Optics*, *Cabinet Cyclopædia*.)

Eriphia (Gr. *ἐρίφος*). A genus of short-tailed or Brachyurous Crustaceans, including the *Cancer spinifrons*, Herbet.; *Cancer conagra*, Fabr.; and other later discovered species.

Eris (Gr. *στρίψε*). In the Homeric and Hesiodic mythology, a daughter of Nyx, the night, and sister of Ares. In the myth of Paris and Eönôn, it is Eris who throws the golden apple, inscribed as a gift for the fairest, on the banquet table of the gods who were celebrating the wedding feast of Peleus and Thetis. Eris is introduced into the Roman mythology under the name Discordia.

Erisma (Gr. *a cause of quarrel*, from its variance with others of its family). The name of a genus of *Vochyaceæ* found in tropical America. One of the species, *E. Japura*, is the Japura of Brazil, a tree growing to the height of 100 feet or more, and bearing a red fruit, the kernel of which is eaten raw or boiled. The kernels are also prepared by being boiled from morning to night, then well covered up and put for two or three weeks into baskets in running water, where they acquire a disagreeable stercoraceous odour; they are then beaten up in a mortar till they acquire the consistence of pale butter, and in this state placed in cylindrical baskets of palm stems. Japura butter,

kept dry by being placed on a stage over the fire, will remain good for two or three years, and is used in gravies. It retains a vile smell, but is said to be savoury.

Ermine. In Heraldry, one of the furs used in blazonry. It represents the skin of that animal white, spotted or timbered with black. *Ermines* is black, spotted or timbered with white. *Erminites* differs from ermine in having the side hairs of the timberings red. *Erminois* is the same as ermine, except that gold is substituted for the white. *Peau* is black, timbered with gold.

Ermine. ('This,' says Gwillim, 'is a little beast less than a squirrel, that hath his being in the woods of the land of Armenia, wherof he taketh his name.') In Zoology, a species of *Mustela*, or stoat, differing from the common weasel in being about one-third larger, and in having a somewhat broader head and a longer tail. In the summer season the upper part of the head, neck, and body, and the greater part of the tail, are of a pale reddish-brown colour; the under parts white, with a very slight tinge of yellow; tip of the tail black, and somewhat bushy. In the winter the whole of the body becomes white, slightly tinged with yellow; but the black termination of the tail is permanent. The fur is closer and finer at this season, especially in the colder latitudes, from which countries the ermine affords one of the most beautiful and valuable of furs. When made up the tails are inserted one to each skin, at regular distances, and in the quincunx order; and thus arranged the ermine fur forms the distinctive doubling of the state robes of sovereigns and nobles, as well as of their crowns and coronets.

Erminois. In Heraldry, a fur in which the field is gold, and the spots or tufts black.

Eroded (Lat. *erodo*, I gnaw off). In Zoology, when a part has its edges irregularly jagged, as if gnawed or eaten.

Eros (Gr. *ἔρως*, love). In Greek mythology, the god of love. In Hesiod, Eros is one of the great cosmogonic powers, along with Chaos, Gæa, and Tartarus. Later poets describe him variously as a son of Hermes and Ares, of Artemis and Aphrodite. His chief characteristic is youthfulness and the power of inspiring the passion of love. In the Veda, Eros appears under the name Arusha, one of the most frequent epithets or names of the sun; but, as in the Greek mythology, Arusha is represented as a child. He is the young sun, driving away the dark night, and awakening the earth with his rays, which later poets converted into arrows, like the lances of Phœbus and Heracles. (Max Müller, 'Comparative Mythology,' in *Oxford Essays* for 1866.) [Isis.]

Erose (Lat. *erosus*, eaten away). In Botany, having the edges irregularly jagged.

Erotic (Gr. *ἔρως*, from *ἔρως*, love). An epithet applied generally to all that relates to or excites the passion of love. In a more confined sense, this appellation has been conferred on a certain class of Greek and Latin

authors, both in prose and poetry, of whose writings love formed the principal theme. Of these the most distinguished are Achilles Tatius, Heliodorus, Anacreon, Sappho, Ovid, Tibullus, Propertius, &c.

Erotomania (Gr. *ἔρως*, and *μανία*, *madness*). Mental aberration, supposed to be occasioned by the passion of love.

Erpetology. [HERPETOLOGY.]

Erpeton. [HERPETON.]

Errata (Lat.). In Printing, the faults that have escaped in the impression, or, as the case may be, in the composition of a work; usually inserted in a list either at the commencement or the end of the book. This manner of indicating typographical errors is coeval with the art of printing itself. Various dissertations have been devoted to this subject; among others may be mentioned that of Lindenberg, *De Erroribus Typographicis*, which, although of a somewhat impracticable nature, contains many ingenious observations.

Errhines (Gr. *ἔρρινος*, from *ῥίς*, *the nose*). Remedies which induce an increased secretion of nasal mucus. When this is accompanied by sneezing, they are called *sternutatories*. They are chiefly used to relieve chronic affections of the eyes, face, and brain, and are perhaps useful on the principle of counter-irritation. [SNUFF.]

Error. In Law, a writ of error is one which authorises the judges of a superior court to examine a record on which judgment has been given in an inferior court, on an allegation of error in pleading or process, &c., and to affirm or reverse the same. It was the common remedy for erroneous judgments, but a memorandum of error is now substituted in many cases. Error lies from inferior courts of record to the Queen's Bench; from each of the three superior courts to the judges of the other two sitting in the Exchequer Chamber; from the Exchequer Chamber, and in certain cases directly, to the House of Lords. It lies in criminal as well as civil cases. Error must generally be brought within six years. Correctly speaking, it is applicable only for the reversal of judgments on account of errors in law, and not of fact.

Erse. The name given by the English and Scots to the dialect of Celtic spoken by the inhabitants of the Highlands of Scotland. The term is evidently another form of the word Irish. The people speaking the Erse tongue call themselves *Gael* (written, but not pronounced, *Gaidheal*), and their language *Gaelig*. England in the Erse language is called *Sassan*, meaning Saxony, and the people and language *Sassenach*; the latter being often called *Beurla*, which means speech in general, and in this case 'the language' *par excellence*. The Irish are called by the Scots Highlanders *Gael*, like themselves, with the distinction of belonging to Erin, or Ireland. For the Welsh and their country there appear to be no names known to the Erse language. The Erse or Gaelic has been asserted to be one of the dialects of that Celtic or Gaulish class of languages which once

pervaded nearly the whole Western portion of Europe, including France, Spain, and Britain, as spoken by the Celtic or first division of the Aryan race which reached Europe. (Max Müller's *Lectures on Language*, 185.)

The only remaining dialects of the Celtic are the Kymric and the Gadhelic or Gaelic, the former comprising the Welsh, Cornish (lately extinct), and the Armorican; the latter, the Erse of Ireland and Scotland, and the Manx dialect of the Isle of Man. These languages agree respectively with each other, not only in grammatical structure, but in that numerous class of words which constitutes the groundwork of every language; viz. prepositions, adverbs, conjunctions, with such verbs, adjectives, and nouns as are of most frequent and familiar use. The Irish and Erse so nearly resemble each other, that after a short familiarity with the pronunciation, the Irish and Scots Highlanders have no difficulty in understanding each other; and the same is said to be the case with the Welsh and the Bas Breton. The Manx is but a dialect of the Irish or Erse, and the now extinct Cornish was unquestionably a dialect of the Welsh. As to the Basque, long supposed to be a Celtic tongue, a careful examination of it by William von Humboldt showed not only that it bore no resemblance to the Welsh, the Irish, or their dialects, but that it had nothing in common with any known language, ancient or modern.

Of the Celtic languages, the Welsh appears to be that which was most cultivated. It was unquestionably a written language in the tenth century; and the perfect alphabet, by which every sound in it is invariably expressed, consisting of sixteen radical and twenty-seven derivative characters, forming in all forty-three letters, is still preserved. The Erse or Gaelic was the least cultivated; and until late years even the Bible which was used in the Highland churches was no other than the Irish. It first attracted notice after the publication in the English language of the poems of Ossian, said to be derived from it, about the middle of the last century. These, it was pretended, were translated from manuscripts in the translator's possession; but such poems in a written form, it is now sufficiently known, never had any existence, either in the Irish or Gaelic language. Although not reduced to writing, or rather not handed down in writing, these poems, committed to memory and thus transmitted from one bard or story-teller to another, still exist in the Highlands of Scotland, and in a dress not unlike that in which they were rendered by Macpherson into English. Their scene is sometimes laid in Scotland, but more frequently in Ireland. In short, they are the *Iliad* and *Odyssey* of the Celtic race of the two islands, handed down by tradition only—what the poems of Homer were to the Greeks themselves, before the art of writing was known to them. The Erse, although a rude and uncultivated language, is a nervous and manly one, both as

ERUCIC ACID

to expression and sound, and well suited poetry, whether sublime or tender. The range of its sounds is very great; for it possesses twelve vowels, and no less than eighteen diphthongs and triphthongs, with forty-one consonants, including aspirates. Many of the consonants are guttural; and of these, as well as of the vocalic sounds, there are several utterly unpronounceable by a stranger: the attempts made to express such a variety of sounds by the Roman alphabet are, of course, both awkward and imperfect. On the affinity of the Celtic to the Teutonic and other classes of the Aryan family of languages, see Max Müller's *Lectures on the Science of Language*.

Erucic Acid (Lat. *eruca*, a plant supposed by some to be *white mustard*). A colourless crystalline body contained in expressed oil of mustard.

Ervum (Lat.; Gr. *ερυθρον*). A family of *Leguminosae*, chiefly remarkable as containing the Lentil, *E. Lens*, an annual with weak branching stems, bearing smooth pods containing a few roundish compressed seeds. These seeds are the Lentils of commerce, much used for food in many parts of the East as well as in Central and Southern Europe. Lentil powder is nutritious, and is said to be beneficial in some cases of indigestion.

Eryngium (Gr. *ἐρύγγιον*, sea-holly). The genus of Umbellifers which yields the Sea Eryngo, *E. maritimum*, a seashore plant with glaucous holly-like leaves, and thistle-like heads of blue flowers. Its fleshy roots are candied, and had once a medical reputation.

Erysipelas (in the opinion of some, from the Gr. *ἐρεσθαι*, to search, and *τέλος*, near—spreading over the neighbouring part but this is doubtful). Called also *St. Anthony's Fire*, that saint having miraculously cured it. This disease usually commences with fever and vomiting, followed by an eruption of a red colour, sometimes vesicular, and attended by tumefaction. It commonly attacks the head and face, and is at its height from the third to the sixth day; but its duration and progress are very variable in different individuals. The fever which attends this form of erysipelas is sometimes inflammatory, and at first cooling diet and aperients are required; the local irritation and itching may be quelled by sprinkling the part with a puff of hair powder (starch), which is singularly soothing to the sufferer. From the eighth to the twelfth day, the eruption scabs or scales off. If sickness, shiverings, and delirium attend the height of the disorder, an unfavourable termination may be anticipated. Sometimes supuration occurs, especially of the eyelids and scalp. The greater number of cases of this disorder have a tendency to debility; and wine, bark, or sulphate of quinia, with other tonics, are indicated.

Where erysipelas is attended with typhoid symptoms, it is dangerous from the beginning; and wine, bark, ammonia, brandy, and other stimulants, are usually prescribed.

ESCALADE

In that form of erysipelas which attacks different parts of the body in successive patches, aperients, diaphoretics, and alteratives are useful; but in every case of this disease, lotions and ointments should be used with the utmost caution. There is a variety of erysipelas which attacks infants, and which is sometimes alarming from its gangrenous or suppurative tendency. Erysipelatous inflammation is also often a sequel of surgical operations, especially in crowded and ill-ventilated hospitals, where it sometimes spreads among the patients to a very alarming extent. Cleanliness, ventilation, fumigation, and, above all, the removal of the affected persons to a better air, are the only chances of eradication.

Erythema (Gr. *ἐρυθμα*, redness). A redness of the skin, generally observed in patches, and sometimes attended with puffiness of the parts affected. It is not attended with febrile symptoms of any consequence, except in a form described as *erythema nodosum*, which is characterised by elevated and somewhat indurated nodules of a red colour rising on the legs, and sometimes on the arms. These generally are more or less oval in shape. The onset of this form is marked by febrile excitement. The treatment consists in the exhibition of purgatives, tonics, and alteratives. Quinia is especially valuable. Ordinary erythema rarely gives trouble, subsiding gradually under mild alterative treatment and rest.

Erythric Acid (Gr. *ἐρυθρός*). Applied by Brugnatelli to the red substance obtained by the action of nitric on uric acid.

Erythrine (Gr. *ἐρυθρός*). One of a series of substances obtained from the *Roccella tinctoria*, a lichen which furnishes the blue dyestuff called *litmus*.

Erythrogen. A peculiar substance, discovered in 1821, by M. Bizio of Venice, in the gall-bladder of a person who died of jaundice. It was a green tasteless liquid, which became deep purple in nitric acid and ammonia, and when heated in the air produced a purple vapour.

Erythronium (Gr. *ἐρυθρός*). A name originally given to the metal since called *Vanadium*, from the red colour of its acid.

Erythrophyll (Gr. *ἐρυθρός*, and *φύλλον*, a leaf). A substance to which the autumnal reddish tint of some leaves is due.

Erythroxyloaceae (Erythroxylon, one of the genera). A natural order of Exogens belonging to the Sapindal alliance. The most remarkable plant it contains is the *Coca*, *Erythroxylon Coca*, common through part of Peru, Quito, and New Grenada, and also on the banks of the Rio Negro, where it is called *Spadie*. This plant is used as a sedative.

Eryx. A genus of serpents with a short obtuse tail and a single series of subcaudal scales, as in *Boa*; but having both the abdominal and caudal scales much narrower, and the anal hooks inconspicuous.

Escalade (Fr. from Lat. *scala*, a stair). The scaling of a fortification by means of ladders is so called.

ESCALLONIAEAE

Escalloniaceae (Escallonia, one of the genera). A small natural order of Exogens belonging to the Grossal alliance, and especially distinguished by its imbricated calyx, its definite style, and its capsular fruit with axile placentae. It yields some ornamental shrubby species.

Escalop. In Heraldry, the scallop-shell used to decorate palmers on their way to and from Palestine.

Escape. In Law, from legal restraint, is either in civil or criminal cases. The former (out of the custody of the sheriff, who has the restraint of the persons of debtors) is either voluntary (by the sheriff's consent, who then cannot retake and becomes himself liable) or through negligence. In criminal cases, the escape of a person lawfully arrested is punishable in various ways, both as regards the person himself and those who may assist him. An escape-warrant is a process addressed to the sheriff to retake an escaped prisoner.

Escapement. In Clock and Watch work, the name given to that part of the mechanism by which the circulating motion of the wheels is converted into a vibratory motion, as that of the pendulum of a clock or balance of a watch. Various contrivances are employed for this purpose, depending on different mechanical principles, as the *dead-beat* escapement, the *lever* escapement, the *duplex* escapement, the *detached* escapement, &c. [HOROLOGY.]

Escarap (Fr. *escarpe*, Gr. *scharf*, *sharp*). In Fortification, the side of the ditch next the place; in which case it is opposed to *counter-scarp*, which is the side next the country. In a fortress, the escarp is generally revetted with masonry.

EscarPMENT. In Geology, the steep face often presented by the abrupt termination of strata where subjacent beds *crop out* from under them. The two most extensive lines of hill which traverse the centre and south of England are formed by the escarpments of the oolite and chalk formations respectively. The first extends through Yorkshire, the West of Lincolnshire, Rutland, Northampton, Warwick, Gloucester, Somerset, Dorset; being bounded throughout on the north-west by the outcrop of the *lias* formation. The latter commences in Yorkshire, rises again in Norfolk, and extends through Cambridge, Hertford, Bucks, Oxford, Berks, Wilts, and Dorset, in a parallel line to the former.

Eschalot (Fr. *échalote*). In Gardening, a small kind of onion, *Allium ascalonicum*, commonly called *Shallot*.

Eschar (Gr. *εσχα*, in the sense of the *crust of a scar produced by burning*). When a living part has been burnt, it becomes hard, rough, and of a grey colour, forming what is properly called an *eschar*: it is a slough produced by fire or caustics. The English *scar* is evidently derived from this term.

Escharotics (Gr. *εσχα*). Applications which form eschars. The term is generally applied in Surgery to mild caustics.

ESCURIAL

Escheat (Nor. Fr. *escheate*, *succession*, from Lat. *cadere*, *to fall*). In Law, happens when tenant in fee simple dies without having left any heir to the land, and without having incurred a forfeiture to the crown (as for treason). This case arises on sentence of death for murder; but not for other felonies, which, since 54 Geo. III. c. 146, leave the power of disposition of his estate after death to the offender. There is no escheat of equitable estates. In practice it is common for the crown, under advice of the Lords of the Treasury, to make voluntary grant of lands escheated or forfeited to relatives of the deceased.

Esclatte. In Heraldry, anything shattered by the stroke of a battle-axe.

Escrow (Fr. *escroue*, A.-Sax. *schrowe*). In Law, a deed delivered to a third party, to be the deed of the party making it upon a future condition when a certain thing is performed, until which it has no effect as a deed.

Escuage or Sontage (from Lat. *scutum*, a shield, the piece of money so called having derived its name from this tribute). A pecuniary satisfaction, paid in lieu of military service by tenants in chivalry. There have been doubts among our antiquarian lawyers whether escuage were, properly speaking, a tenure in itself, or merely an incident to tenure; but the latter is probably its proper character. Littleton says, that tenant by homage, fealty, and escuage is tenant by knight service. The assessment of escuage was uncertain in amount, and, by Magna Charta and 25 Edw. I., could only be taken by assent of parliament. Escuage, together with the other appendages of military tenures, was abolished by 12 Ch. II. c. 24.

Esculic Acid. [SAPONIC ACID.]

Esculin. *Polychrome*. A neutral crystalline substance found in horse-chestnut bark. It possesses the property of *fluorescence* in a high degree; one part in a million parts of water appearing blue by reflected light.

Escorial (Span. *Escorial*). A royal palace of Spain, about twenty-two miles from Madrid, at the foot of the mountains which divide the two Castilles. Its foundations were laid by Philip II. in 1563; Juan Bautista of Toledo being the architect who designed, and continued to superintend, the building till his death in 1567, when his pupil Juan de Herrera carried it on, being assisted by Antonio de Villacastin. It is considered by Spaniards as the eighth wonder of the world, and numberless fables are told about the domes, windows and columns, which are said to be innumerable; as well as its cost, which is said to have been twenty-four millions of ducats; but this is much exaggerated, as it cost only about a quarter of that sum. The whole pile comprises a magnificent monastery, which was given to the fathers of St. Girolamo, a college, a seminary, and a royal palace. It is internally disposed into fifteen courts of various dimensions, the largest being ornamented with porticoes and galleries; the material employed is a species of granite which the Spanish masons

ESCUTCHEON

work with surprising dexterity. The principal façade, looking towards the west, is 740 feet long, and 70 feet high to the cornice; and at the extremities are erected towers 200 feet high. From the centre of the church a cupola rises, of a good form externally, but clumsily composed inside; its diameter is 66 feet from the pavement to the top of the cross, the height 330 feet. The burial-place for the Spanish royal family is called the Pantheon, and is the crypt under the chapel, situated immediately below the high altar. On the two inferior landings of the staircase which leads to it are two doors, one leading to the vault where are laid the remains of the infants and infantas, and of the queens who have had no issue; the other to the chamber, 36 feet diameter and 38 feet high, where the remains of the kings are deposited. The whole of the building is profusely ornamented, particularly with paintings by the best masters of Italy, Flanders, Spain and Germany. Attached to the monastery by an arched doorway is an edifice called the Campana, which has two galleries, each of them 100 feet long and 20 feet wide. This was built by Francesco de Mora, the third architect who succeeded Juan de Herrera. Here are the hospitals, granaries, pantries, and other offices, with the gardens. Adjoining the eastern and northern façades is a spacious gully or esplanade, surrounded by a parapet; on this side are the quarters for the guards, the riding school, the aqueduct, &c. &c. In 1773 many works were executed at the Escorial, for the infants Don Antonio and Don Gabriel, by Villanueva, the then architect of the palace; indeed, all the successors of Philip II. have made additions to this superb edifice, which exhibits with great beauties great defects. (See the *Descripción del Real Monasterio de San Lorenzo del Escorial*, by Fray Andres Vimenas, which has been translated into English by Thompson; and Mr. Ferguson's criticisms in his *History of Modern Architecture*.)

Escutcheon or **Escoccheon** (Old Fr. *escusson*, dim. of *escu*, Ital. *scudo*, Lat. *scutum*, a shield). In Heraldry, a shield on which arms are emblazoned: derived from the French *écu* or *écusson*, Italian *scudo*, Latin *scutum*. The favourite shape for the purpose of heraldry is that commonly called the Norman shield; but women, daughters of parents entitled to coat-armour, bear their father's arms on a lozenge-shaped shield. The points of the escutcheon are the parts named in order to express the local position of the charges borne on the field. [CHARGE.] They are nine in number. *Escutcheon of pretence* is the shield on which a man carries the arms of his wife; in England only borne if she is an heiress, and he has children by her. It is borne in the centre of his own shield, and generally of the same shape. *In-escutcheon*, an escutcheon borne also within the shield in the middle of the coat (but smaller than an escutcheon of pretence), or in chief. It is a species of ordinary.

ESQUIRE

Esmarkite. A species of Datholite, or borosilicate of lime, discovered by Esmark at Arendal.

Esocidae (Lat. *esox*, the pike). The *Pike* tribe, a family of *Malacopterygious* or soft-spined fishes, having the ventral fins placed under the abdomen, and including most of the voracious fresh-water fishes, as well as several marine species.

Esoteric (Gr. *ἐσωτερικός*, inner), opposed to **Exoteric** (Gr. *ἐξωτερικός*, outer). Much dispute has prevailed among the learned as to the precise import of this distinction. By some it was thought that the ancient philosophers had a set of mysterious doctrines which they communicated only to the more enlightened of their disciples, and another more popular doctrine which they promulgated to the multitude. In the case of Aristotle, to whose writings the distinction properly applied, this opinion is, to a certain extent, well founded; except so far as regards the suspicion of intentional concealment implied in it. The exoteric or published writings of that philosopher appear to have been written in the form of dialogues, all of which are lost. His esoteric works, we gather from the synonymous term *acroamatic*, were not intended to supersede the necessity of oral instruction to render them intelligible. This agrees well enough with the brevity, the frequent repetitions, and the perplexed arrangement of the works of Aristotle which survive. [ACROAMATIC.]

Espalier (Fr. from *palis*, a pale or pole). In Horticulture, a substitute for a wall on which to train fruit-trees, and sometimes ornamental shrubs. The objects are to expose the foliage of the plants more perfectly to the light, to prevent the branches from being blown about by the winds, and to economise space by confining them within definite limits. The espalier is either constructed of wood or iron; and commonly of two horizontal rails joined by upright rods, six or eight inches apart.

Esparto (Span.). A species of grass, the *Stipa* or *Macrochloa tenacissima*, found in the southern provinces of Spain. It is made into cordage, much used in the Spanish navy; and is plaited for other purposes, such as mats, shoes, &c. Spanish grass is now largely imported into Great Britain for making paper.

Esplanade (Fr.). In Fortification, an open space of ground left outside the glacis of a work to prevent an enemy erecting breaching batteries under cover of buildings.

Esponsals (Lat. *sponsalia*). In Law, a contract of marriage. [MARRIAGE.]

Esquire, **Seuyer**, **Escudero**. A well-known title of rank; derived from the Fr. *écu*, *escu*, Lat. *scutum*, a shield. Some suppose that it has its origin from the *scutarii*, a sort of soldiery in the Roman armies; others derive it from *equus*, a horse, and suppose that esquire and querry denoted originally the same thing, viz. a groom. But it is generally supposed to have belonged to the shield or armour bearers (*armigeri*) attached to the person of knights

This office, in the times of chivalry, was honourable, and generally borne by persons of good family. Hence the term *esquire* became gradually appropriated, in England, to a rank above the simple gentleman and below the knight. Younger sons of peers (now called *honourables*), their eldest sons, eldest sons of knights, sheriffs of counties, sergeants at law, justices of the peace, and doctors of divinity, are esquires by virtue of their respective rank or office. Heads of ancient families are considered esquires by prescription; and hence has originated the use of the word, in the present day, as a common addition to the name of all those who live in the rank of gentlemen. According to ancient usage, the king creates an esquire, by putting round his neck a silver collar of *ff*; to which ceremony was added the putting on of a pair of silver spurs.

Essay (Fr. *essai*). In Literature, an attempt at a species of composition. In general, this title is given to short disquisitions on subjects of taste, philosophy, or common life. In this sense it has been applied to periodical papers, published at regular intervals under a collective name, by one or more writers, containing remarks on topics of the day or on more serious subjects. From the appearance of the *Tatler*, in the beginning of the last century, which was chiefly written by Sir Richard Steele, this species of literature continued to be a favourite in England for seventy years, and many similar series of essays were produced: the best of which are united in one collection under the name of *The English Essayists*. The most celebrated of these works was the *Spectator*, to which Addison was the best contributor; and next to it the *Rambler*, published and almost wholly written by Samuel Johnson. The title of *essay* has been also adopted, by way of indicating diffidence in the completeness of their work, by various authors of more extended performances; as by Locke (*Essay on the Human Understanding*).

Essence (Lat. *essentia*, from *esse*, to be or exist). In Philosophy, a scholastic term, denoting what the Platonists called the idea of a species. The school philosophers give two significations of the word *essence*: the first denoting the whole essential perfection of a being, and consequently its entity, with all its intrinsic and necessary attributes taken together; the second denoting the principal or most important attributes of any thing. The essences of things were held by many to be uncreated, eternal, and immutable. [METAPHYSICS.]

Essence d'Orient (Fr.). A term applied to a pearly-looking matter found principally at the base of the scales of the *bleak*, a small fish of the genus *Cyprinus*: it is used to line the interior of glass bubbles or beads, as in the manufacture of artificial pearls.

Essenes. A sect among the Jews in the time of our Saviour, of whom an account is preserved to us by Josephus and Philo, though

they are not mentioned in Scripture. They were few in number, and lived chiefly in solitude, taking no part in public affairs, but devoting their lives to contemplation. There were indeed two classes of them, distinguished as the practical and contemplative, who differed in the degree of strictness and austerity which they observed. They believed in the immortality of the soul, and held the Scripture in the highest reverence, interpreting it after an allegorical system of their own. The whole subject, however, is involved in such obscurity, that De Quincey was able with some plausibility to propound the theory that the so-called Essenes were in reality the Christian community.

Essential Oils. The essential or volatile oils may be regarded as the odorous principles of vegetables, and are generally obtained by distilling the plant with water, either in its fresh, salted, or dried state. In some cases they are pressed out of the cellular structure, as from orange and lemon peel. They are obtained from all parts of plants, though usually most abundant in the leaves and flowers; and they sometimes differ in different parts of the same plant: thus, in the orange-tree, the leaves, flowers, and fruit, each yield a distinct oil. Some of them are so delicate and evanescent as to require a peculiar mode of treatment, such as those of the flowers of jasmine, tuberose, narcissus, mignonette, &c. These flowers are stratified with layers of cotton, or wool, imbued with some inodorous fixed oil, which absorbs the perfume of the flowers. When the fixed oil is saturated with the perfume, it is digested in alcohol, which abstracts the essential from the fixed oil, and an odoriferous *essence* is obtained. Sometimes the cotton is distilled with water or alcohol to separate the odorous essence; but the fragrance is always more or less impaired by these processes.

The essential oils are applied to many useful purposes: some in the manufacture of paints and varnishes, some for burning in lamps; others in pharmacy and medicine, and others in perfumery. They are mostly ready formed in the plant, but they are in some cases generated by the action of water upon peculiar principles, as in the production of bitter-almond oil; and here are a few instances of their artificial production, as in that of *oil of spirea*, by the oxidation of salicine. When fresh and pure, these oils are mostly colourless or nearly so; a few are green or blue, and some after having acquired colour, lose it under the influence of light. Their odours resemble those of the plants yielding them, but are less agreeable, partly in consequence of concentration, for they become more pleasant when diffused in the air, or when attenuated by solution in some inodorous vehicle; they are also influenced by their chemical relations to air and water. Some oils, such as those of turpentine, lemons, and uniper, when distilled off quicklime, out of contact of air, are nearly inodorous, but which acquire their characteristic odours when spread upon paper.

ESSENTIAL OILS

The specific gravity of the essential oils fluctuates between 0·840 and 1·100, and when subjected to a careful fractional distillation, they are mostly resolvable into products differing in specific gravity and in composition; one of which is frequently a *hydrocarbon*, and the other an *oxyhydrocarbon*, which is sometimes concrete, constituting a species of *camphor*. The terms *elaiophens* and *stearophens* have been applied to these liquid and solid products (from *elaion*, oil, or *στάειν*, fat, and *πυρός*, volatile). Their boiling points are variable, and so are the temperatures at which they congeal, these being often dependent upon the relative proportions of their component oils. They are sparingly soluble in water, to which, as in the medicated waters of the *Pharmacopœia*, they communicate odour and flavour; most of them are copiously soluble in absolute alcohol and in ether, and in fixed oils and liquid hydrocarbons. In consequence of the high price of many of these oils, they are sometimes adulterated with alcohol, with fixed oils, or with cheaper essential oils. Alcohol may generally be separated by shaking the adulterated oil with water, and its quantity appreciated by the diminution in the bulk of the original oil. Moreover, the pure volatile oils dissolve, for the most part, in the fixed oils, without interfering with their transparency; but when adulterated with alcohol they produce turbidness. The admixture of a fixed oil is shown by the greasy stain which remains on evaporating a drop of the oil before the fire, from a piece of blotting-paper: some of the genuine oils leave a stain, but it is rather resinous than greasy, and admits of being written upon with a pen and ink, or removed by alcohol. The feel of the adulterated oil between the finger and thumb is also greasy, and when it is distilled with water, the fixed oil remains in the retort. The adulteration of a high-priced with a cheap essential oil is often difficult of detection, and requires experience in the odour and qualities of the genuine article. When oil of turpentine is so used, its characteristic odour is often covered, until the adulterated oil is dissolved in a little alcohol, and water added, when the odour and flavour of the turpentine are manifest. The difference between the indices of refraction of the adulterated and genuine oils has been proposed as a means of detecting falsifications, and Dr. Wollaston suggested an instrument for the purpose (*Phil. Trans.* 1803); but the refractive powers of the genuine oils vary too much to render this method satisfactorily available.

For the purpose of chemical description, the essential oils may be arranged under three divisions: 1. Those composed of carbon and hydrogen; 2. of carbon, hydrogen, and oxygen; 3. those containing sulphur.

1. **HYDROCARBONS.**—The elementary composition of this group may be represented by C_nH_m ; it includes many isomeric compounds, of which oil of turpentine may be assumed as the type. Oil of turpentine $C_{10}H_{16}$ (*camphens*; *camphyl*) is obtained by distilling the

ESTAFETTE

turpentine of commerce with water. It is a colourless and very mobile liquid; specific gravity 0·865, boiling at 212° , and yielding a vapour of the density of 4·764. It has a characteristic odour, a hot pungent taste, and burns with a large sooty flame: it is almost insoluble in water, but soluble to some extent in alcohol and in ether. Under the name of *camphens* it was at one time largely used as a source of light, and when carefully burnt in a properly constructed lamp, gives a brilliant flame; but if the oil is not fresh, and has been exposed to air, it clogs the wick, and smokes. Its use has lately been superseded by *rock-oil* and other modifications of naphtha.

2. **OXYHYDROCARBONS.**—The essential oils containing oxygen are very numerous. Some of them, when distilled, are separable into a more volatile hydrocarbon and a less volatile oxyhydrocarbon. Oil of *cumin*, for instance, may be resolved into a hydrocarbon— $C_{10}H_{14}$, *cymol*, and an oxyhydrocarbon— $C_{10}H_{12}O_2$, *cuminol*. Oil of *aniseed* is similarly separable into a hydrocarbon and an oxyhydrocarbon.

3. **ESSENTIAL OILS CONTAINING SULPHUR.**—There are several essential oils which contain nitrogen and sulphur, amongst which the oil of black mustard-seed, garlic, asafoetida, and horseradish, are the most remarkable; they are fetid, and blacken silver.

Essoign (Fr. *ensoigne*, *essoign*). In Law, an excuse for one who is summoned to appear and answer an action or perform suit in a court, &c., by reason of sickness or other prevailing cause. The first return day in every term was called the *essoign* day, because the court sat on it to take *essoigns*; i.e. excuses for such as did not appear according to the summons of the writ. The *essoign* day seems to be done away with by the effect of the statutes 11 Geo. IV., 1 Wm. IV. c. 70, 1 Wm. IV. c. 3.

Essonite. A mineralogical synonym of the *Cinnamon Stones* of Ceylon: it is a silicate of lime, alumina, and oxide of iron.

Essorant (Fr. *essor*, the soaring of birds). In Heraldry, a term for a bird standing with its wings expanded, as if drying itself.

Establishment. [*Foundation*.]

Establishment of the Port. A term used by writers on the tides, to denote the interval between the time of high water at any given port and the time of the moon's transit immediately preceding the time of high water, when the moon is in syzygy; that is, at the new or full moon. This interval is influenced by local circumstances, and consequently different at different places. [*Times*.]

Estafette (Fr.; Span. *estafeta*). Applied originally to military couriers, but now used in all the countries of modern Europe to signify an *express*. The difference between a courier and an *estafette* consists in this, that while the courier must deliver the despatches, &c. intrusted to him personally at the place to which they are addressed, in the *estafette* the despatches, letters, &c. to be forwarded are consigned to the care of postillions, who are

ESTATE

changed with every relay of horses successively till they arrive at the place of their destination.

Estate. In common parlance, this term is applied to the landed property held by individuals; and a man is said to be of good or of small estate, according to the magnitude of his landed property.

The comparative magnitude of estates, in other words, the number of persons possessing land in different countries, and the method by which the occupancy of land is characterised, are questions of great interest in connection with what economists call the distribution of wealth. This interest is contained not only in the general fact, that in a given population the existence of great wealth in some hands implies great poverty as the lot of others, particularly where the industry of a country is turned especially towards agricultural pursuits; but because by a natural process political influence is invariably connected with the tenure of land, and possessed in a measure by those who hold land disproportionate to the numerical value of the real estate and its profits. The landowners of a country are ultimately its rulers; and a community is invariably led into that political constitution which is most congenial with the habits and interests of the owners of its soil.

Of the number of landowners in England we are quite ignorant; no registration of land, except in two counties, Middlesex and York, having been customary in this country. For a short period, that is during the time in which the Statute of Enrollments was operative, such a registration was in course of creation; but the devices of lawyers, and the desire of secret conveyance on the part of landowners, rendered the statute nugatory almost from its commencement. We may be certain, however, that the number is decreasing, as the power which the practice of primogeniture and the privilege of strict settlement give, of creating what is virtually a perpetual entail, tends to agglutinate properties into vast estates, by precluding the possibility of division, as well as by giving facilities for acquisition. According to the latest returns, the annual income of real estate in England and Wales is upwards of 120,000,000*l.*; in Scotland and Ireland it is nearly 30,000,000*l.*

In France it has been calculated that the cultivated soil is divided among about six millions of proprietors, five millions of whom possess estates of no more than an average of three hectares, or seven and a half acres. The question, however, whether the number of occupiers increases or diminishes in France, is still open and debated. The reader will find sufficient information on the subject in Mr. Frederic Martin's *Statesman's Year Book*.

Estate. In Law, the legal quantity of the right of property in the individual, as for years, life, &c.; thus one having an interest which will devolve on his heirs is said to have an estate of inheritance. [FEE SIMPLE; FEE TAIL.]

Estate for Life. In Law, a freehold interest in lands and tenements, whether en-

ESTOPPEL

joyed for the life of the tenant, or for the life of another party (in which latter case it is termed an estate *pur autre vie*). This species of interest includes estates granted for an uncertain period limited within the duration of a life; as, for instance, an estate granted to a widow during her widowhood. If lands are granted by deed to one without mentioning his heirs, he takes an estate for life only, though a similar gift in a will would now confer the fee simple. If tenant for life conveyed an estate greater than his own by feoffment, fine, or recovery, he formerly forfeited his estate; but no conveyance by him can now so operate, or do more than create an estate determinable on his own death. With respect to estates *pur autre vie*, it is observable that, formerly, when lands were given to A for the life of B, if A or A's assignee happened to die in B's lifetime, the estate belonged to the first person who could take possession, termed an *occupant*; but if given to A and his heirs for the life of B on the same event, A's heir succeeded as special occupant. Now, by the Statute of Frauds (see 7 Wm. IV. and 1 Vict. c. 26), estates *pur autre vie* are devisable; and, if there be no special occupant, they go to the executors or administrators of the deceased, and are applied or distributed as if part of his personal estate.

Estate for Years. In Law, an estate limited for a term of years, or other determinate time, in lands, tenements or hereditaments, is a chattel or personal interest; and on the death of the owner, devolves, like other personal property, on his executors or administrator. An estate for years is properly created or *demised* by an instrument termed a *lease*; which, at common law, has not full operation until the entry of the tenant. It may also be created by declaration of use, or by devise in a will; and may be made either to commence immediately, or on a future day and event: in which latter case, unless there be any particular estate to support it as a remainder, it is called an *interesse termini*, until the time arrives for its reduction into possession. Covenants between the lessor and lessee relating to the land (which are usually inserted in the lease) are said at common law to run with the land: they pass, along with the term of years, to a party to whom the lessee conveys it by assignment; but the lessee's covenants do not pass to a party to whom he conveys part of the term by underlease. A tenancy from year to year is a species of estate for years.

Estates, Political. [STATES.]

Estoppel. [ESTOPPEL.]

Estoppel (Old Fr. *estouper, to stop*). In Law, an impediment or bar to a right of action, arising from a man's own act, or that of one to whom the party estopped is privy. As, if a party is bound by a particular name in an obligation, and afterwards sued by that name on the same obligation, he is estopped, i. e. forbidden in law to say in abatement that he is misnamed; as he cannot say contrary to that

ESTRADE

which he has admitted by his own deed. All parties to a deed are estopped to say anything against what is contained in it; and privies are also bound.

Estrade (Ital. *estrada*). The portion of the floor of a room raised two or three steps above the general level, for the purpose of receiving a bed or throne; it is used now for any portion of a raised floor.

Estreat (Lat. *extractum, a thing taken out*). In Law, the extract copy, or, note of some original writing or record, and especially of fines and amercements, entered on the rolls of the court, to be levied by its bailiff or other officer. Fines to the crown are *estreated* into the Court of Exchequer, connected with which court there is a special officer called the *queen's remembrancer*, in whose office many matters relating to the crown revenue are transacted. Provision is made for the due return, *estreating*, and levying of fines, &c. in the superior and some other courts by 3 & 4 Wm. IV. c. 99 and 22 & 23 Vict. c. 21 s. 23.

Estrioh. The commercial name of the fine down of the ostrich.

Estuary. [*ÆSTUARY*.]

Et Cætera (Lat.). In Printing, usually expressed by the sign *&c.*, means *and so on*. It was formerly properly printed *&c.*, an obvious form of *etc.*

Estræio (Gr. *στράιος, a companion*). In Botany, an aggregate fruit, having the ovaries distinct, and the pericarp indehiscent. It is either dry upon a fleshy receptacle, as the Strawberry; or dry upon a dry receptacle, as the Ranunculus; or fleshy upon a dry receptacle, as the Blackberry: the parts being achenes or small drupes.

État, Coup d'. This French phrase denotes a sudden political move or stroke in order to subvert an existing state of things without the risk of a prolonged contest. The present emperor of the French resorted to such a measure, when, on December 2, 1852, under the pretext of 'saving society,' and contrary to the terms of the oath taken by him before entering on his office, he virtually suppressed the constitution of the Republic, of which he was the president. It is significant that the English language furnishes no phrase for such measures.

Etching. [*ENGRAVING*.]

Etching Needle. An instrument of steel, with a fine point, for tracing outlines &c. upon the copper plate.

Etean Winds. [*WINDS*.]

Ethal. A substance formed during the saponification of spermaceti. Chevreul coined the name from the first syllables of *ether* and *alcohol*, on account of its analogy to those liquids in point of composition.

Ether (Gr. *αἰθήρ*). In Chemistry, this term is applied to a highly volatile, fragrant, inflammable, and intoxicating liquid, produced by distilling a mixture of equal weights of sulphuric acid and alcohol. When these liquids mutually act on each other, a series of compli-

ETHERS

cated changes ensue, which terminate in the conversion of the alcohol into ether. Ether, like alcohol, may be regarded as a compound of hydrocarbon and water; and if alcohol be considered as consisting of *one* equivalent of olefant hydrocarbon=14, and *one* of water=9, ether may be regarded as constituted of *two* of olefant hydrocarbon (14 x 2)=28, and *one* of water=9: hence, the equivalent of alcohol being 14+9=23, that of ether will be 14 x 2=28+9=37; and the process of etherification may be stated to consist in, the abstraction from alcohol of one-half of its elemental water. By some, ether is regarded as the oxide of a peculiar hydrocarbon, which they term *ethyl*, composed of 4 equivalents of carbon and 5 equivalents of hydrogen; and alcohol must in that case be considered as hydrate of ether.

Ether, or, as it is often called, to distinguish it from analogous products obtained by the intervention of other acids, *sulphuric ether*, is a limpid colourless fluid, of an agreeable odour, and a hot pungent taste. Its specific gravity is about 0.713, though that of the shops is usually heavier; it boils at about 98°, and freezes at the low temperature of 46° below 0°. The specific gravity of ethereal vapour compared with atmospheric air is as 258 to 100. Ether is sparingly soluble in water, which takes up about a tenth of its bulk; it dissolves in all proportions in alcohol. The principal use of ether is in medicine. When taken internally, it is stimulant; and it is sometimes applied externally, in consequence of the cold produced during its evaporation, as an ingredient in refrigerating lotions. Ether was at one time much used as an anæsthetic, but in this respect it is superseded by chloroform.

Ethereal Salts. Combinations analogous to metallic salts, the metal being replaced by a compound organic radical, such as ethyl. They are generally colourless, volatile, and have a peculiar and powerful odour. Many of them resemble, and are probably identical with, the odoriferous and flavouring principles of edible fruits.

Etheria (Gr. *αἰθήρες*). A genus of Lamellibranchiate Dimyary Bivalves, with a large ventral muscular plate or foot, as in the *Uniones*; but having their shell adherent, as in the oyster, to foreign bodies: the hinge is toothless, irregular, undulated, and callous; the ligament external, but penetrating in a pointed form into the interior of the shell. The term *Etheria* has also been applied by Rafinesque to a genus of Macrourous Crustacea.

Etherin. A name applied by some chemists to quadrihydrocarbon; that is, to an hydrocarbon, 1 atom or equivalent of which is constituted of 4 atoms of carbon and 4 of hydrogen.

Etherine or Ethereal. *Light oil of wine.* volatile oily hydrocarbon formed during the preparation of ether.

Ethers. Oxides of organic positive radicals of which common ether (*oxide of ethyl*) is the type. They are generally volatile liquids; one,

however, is gaseous (methylic ether), and a few are solids. Ethers are generally neutral to test paper, but act as bases to acids, the resulting compounds being ETHERIAL SALTS. *Haloid ethers* are combinations of non-metallic elements, other than oxygen, with positive organic radicals.

ἠθικός (Gr. *ἠθικός*, from *ἠθος*, *moral temper*).

The science which treats of the laws of voluntary action, and thus seeks to determine the nature and extent of moral duty. The several systems of ethical philosophy are conveniently divided into ancient and modern. The distinction, however, is not founded on any essential difference of theory, but rather on the opposite points of view from which they respectively viewed the subject-matter of the science. While modern theories are permanently subjective, the objective question is the characteristic feature of ancient ethics. The leading speculation of the former is: What is the origin and nature of moral obligation? The first problem of the latter was to determine the object or end to which the moral constitution of man has reference, and this ultimate end of human activity they usually denominated the end or sovereign good (*τέλος*, *finis bonorum*, *summum bonum*). And although the consideration of this question might tend in a few, as in Socrates and Plato, to carry the mind forward to some higher and ulterior existence, in which should be realised that entire satisfaction after which man aspires, still, as these promptings of natural religion were but vague and unauthoritative, the ethical writers of antiquity confined their views to this life alone, and the sovereign good which they proposed as the final cause of moral action was limited to the greatest good attainable in the present state of existence.

With Socrates, the first object of speculation was to acquire a knowledge of man's true and proper nature; but this self-knowledge he held to be impossible so long as man continues ignorant of the universal principle. Now the nature of God can only be learnt from His works, and these bespeak Him to be good and intelligent. Moreover, the consciousness of man attests his participation in the divine essence; consequently the ultimate destination of man is reason and goodness, and his moral end is the cognition and practice of good. Virtue, therefore, is the intelligent performance of duties, a knowledge of which man may arrive at by a study both of his own nature and of the laws of an all-wise Creator discoverable in the system of the universe. In this pursuit happiness is inseparable from virtue. But if Socrates thus founded morality on a disinterested principle, he reconciled it with interest rightly understood; and on the other hand raised political science above the mere calculation of utility, by identifying it with justice as founded not on convention (*ἰσχυρὰ τέλει*), but on natural right, or the invention of what is (*οὐκ ἔστιν ἰσχυρὰ*).

Thus the ethics of Socrates, in their close

connection with political science, had the same foundation of fact with the Baconian philosophy. It was in his belief a strictly inductive, and not a deductive science; and, to understand his system aright, it is essential to remember that on this ground alone he insisted on the superiority of moral over physical science. Nor could it well have been otherwise, if we consider the slender amount of experimental knowledge which had been attained in his day. In the field of the natural sciences, Socrates saw nothing but a Babel of conflicting speculations. While Heraclitus taught that the light of the stars was fed by exhalations from the earth, Zeno-phanes held that they were fiery clouds, lit at night and put out in the morning. According to Parmenides the earth was spherical, and placed at the centre of the universe; while Anaxagoras held that it was a plane, and Anaximenes believed that its form of a flat trapezium prevented it from sinking in space. Astronomy, therefore, 'now exhibiting the maximum of perfection, with the largest and most exact power of predicting future phenomena which human science has ever attained, was pronounced by him to be among the divine mysteries which it was impossible to understand and madness to investigate.' (Grote, *History of Greece*, viii. 5, 77.) Thus, turning away from sciences which started with a theory and reasoned in support of it, Socrates confined himself to that field of human practice which he felt that men were competent to examine, while the very fact that men could examine it to some purpose proved convincingly that 'the proper study for mankind is man.'

Socrates having thus referred the laws of morality to the Deity as their author and upholder, Plato proceeded by a definition of the divine nature to guard against the objection of their arbitrary position by the will of God. He made the Deity to be the perfection of intelligence *as* resulting from a union of the good, the beautiful, and the true, which are in their nature eternal, necessary, and immutable. This perfection is also the term to which man spontaneously tends. For reason is the true principle of his nature, although in the present existence there is mingled with it a foreign element—*matter*, which, by obstructing its development, becomes the cause of his falling short of perfection. All, then, that is now possible for man is an approach to the divine excellence. This is virtue, and is effected by the harmony of the *rational*, *irascible*, and *concupiscible* parts of the soul. Although the two latter belong to the foreign element in man's nature, they are yet indispensable to the moral act: for the third affords a motive to action, inasmuch as beauty, being identical with the good and true, gives rise to desire or love (*ἔρως*), and thereby impels to virtuous action; while the second, disapproving what is base, unseemly, and false, furnishes the *fortitude* requisite for attaining to what is approved under every difficulty and every discouragement. To each of the three parts of the

ETHICS

soul Plato assigns a special virtue, in a lower sense, and names them, respectively, *prudence*, *fortitude*, and *temperance* (*φρόνησις*, *ἀνδρεία*, *σωφροσύνη*), while in a proper sense he declares virtue to be eminently one and the same with justice (*δικαιοσύνη*). These four are the so-called cardinal virtues. From the notion of justice he draws the connection of ethics and politics: the latter is but an application of the former to society. At the close of the *Republic* he teaches that as an individual cannot be at peace with himself except by the harmonious adjustment of all his faculties, wherein each is allowed its due weight, so in the whole world happiness is proportionate to justice, and each individual derives the greater benefit from the community the more complete the harmony is in which he lives with all his fellow-citizens.

Essentially agreeing, the ethical systems of Plato and Aristotle are chiefly distinguished by the relative value which they respectively ascribe to happiness; the former considering it as the natural fruit of virtue, while the latter rather viewed virtue as the means of attaining to happiness. Plato taught, that although the just-man regulates his conduct by no reference to his own enjoyment, yet pleasure invariably attends him, since justice is good not only in itself, but also in its effects, and renders all things fitting and friendly to man. In Aristotle's opinion, the end of morality is to render individuals as useful as possible to society, society being instituted in order to procure in its members the highest moral perfection, as necessary to the attainment of the greatest possible felicity by the whole. Man, he teaches, is a free and rational agent, and therefore acts spontaneously and deliberately, invariably proposing to himself some end as the motive to action. All human arts and pursuits, then, have their appropriate ends; but among these there is a certain subordination, which implies a supreme and towards which they all converge, this end being the cause for which all else is sought. This supreme good is happiness (*eudaimonia*): virtue is the approximation thereto, and consists in the habit of mediocrity according to right-reason; in other words, it is self-control, which triumphs alike over the impetuosity of the passions and the weakness of the will, and thereby accomplishes a just mean. Every special virtue, in like manner, lies in a kind of middle between the two opposite vices of excess and defect: courage, for instance, being a mean between cowardice and rashness, of which the former offends by an excessive, the latter by a defective, regard to the proper objects of fear.

According to the Stoics, the supreme good which is the final cause of every special good is to act conformably to nature; i. e. in obedience to the immutable laws which reason discovers in the universe. This eternal and universal order, which they called *fate*, is an infinite enchainment of causes and effects, in virtue of which whatever happens is what

ought to be: it embraces all living things, and man therefore has a principle within him which obliges him to seek that state of his nature which is the best and most perfect that it is capable of. This is reason. Wisdom, therefore, is man's chief good, and the pursuit of it is philosophy. Perfect wisdom, however, as modelled in the ideal sage of the Stoics, they did not believe to be conceded to mortals, to whom nothing more is granted than to be in *the way* to perfection. Now, as they made reason to be the supreme arbiter in moral determinations, they naturally held vice to be but an error: yet this error, they taught, is the only evil; and, on the other hand, nothing is good but what is such in all times and all circumstances: all else is morally indifferent. But even indifferent things are, in a lower sense, agreeable to nature, and objects more or less of choice or aversion. That perfect rectitude of conduct, therefore, which constitutes the essence of virtue, consists in a just and accurate discernment of good, and in assigning to every object its due importance according to the place it holds in the natural scale of things. Lastly, although their first object was to emancipate the moral man from all dependence on external conditions and from the slavery of his passions—and although, therefore, they removed all sensuous pleasures and pains from the catalogue of good and evil—nevertheless, the apathy which they taught was not, as commonly understood, an absolute insensibility, but rather the undisturbed supremacy of reason over the passions.

All the preceding theories agree in making reason the end of human activity, and are thereby distinguished from the Epicurean, which gave the first place to the sensuous element of humanity, and reduced science to the rank of a mean. According to Epicurus, pleasure alone is sought for its own sake, and philosophy and all else is but the pursuit of it. If, sometimes, it seems to be foregone, it is only with a view to some higher gratification, as pain also may occasionally be endured in the acquisition of a pleasure whose intensity will fully compensate for the intermediate suffering. The pleasures and pains that are primarily the objects of desire and aversion are corporeal, and from these the pleasures of the mind are ultimately derived, and consist merely in the anticipation of future and in the recollection of past states. This, however, constitutes the superiority of the secondary pleasures of the mind over their corporeal originals, for the latter do not extend beyond the present sensation. *Virtue*, therefore, is an enlightened pursuit of pleasure, which, although it is selfish in its principle, still allows free course to the social and benevolent affections, as being a part of man's nature and an additional source of gratification beyond the calculations of personal interest. For though they may expose a man to the chance of pain, as in the case of the death of a friend, still this is a less evil than apathy, and the deprivation

of a natural enjoyment. Justice, lastly, has no other object than the general good; and right, properly understood, is but the sign of utility.

Modern ethics having taken their rise from a system greatly resembling the Epicurean, the enquiry into the nature of virtue became the first question that was proposed for solution. Accordingly this fact furnishes a general classification of the later theories of morals into selfish or disinterested, according as they found virtue on a selfish or on a benevolent principle.

The selfish theory has found its ablest advocates in Hobbes, Helvetius, Paley, and Bentham. Of these the first and last deserve a particular notice: Hobbes as the originator of the controversy into the nature of morality; Bentham as furnishing the most complete and elaborate exposition of the utilitarian scheme. According to Hobbes (born 1588, died 1679), the only motive that can induce men to any act is the pleasure which will follow from its execution. A preconception of pleasure is the necessary condition of every moral determination. Good and evil are simple tendencies to pleasure and pain, without which every object is indifferent. Self-love is the exclusive passion of man's nature. Other passions differ from it outwardly only, i.e. in the objects which excite them: pity, for example, is but the imagination of misfortunes which may happen to ourselves, suggested by the contemplation of another's sufferings; love, the conception of advantages to be derived from its object; and benevolence, nothing more than the consciousness of power sufficient to secure not only one's own happiness, but that of others also. The first law of nature is self-preservation: whatever tends, therefore, to this end is lawful and good, and all men have a natural right to appropriate by every means in their power whatever may contribute to their personal happiness. As this is the imprescriptible right of all, there are as many forms of natural right as there are separate and independent wills; and actions of the most opposite kinds are equally virtuous and legitimate. Now, as all possess an equal right to all things, and as there is no reason why one should yield to another the objects which both may desire, the state of nature must be one of war; but as, in such a condition of things, the safety of everyone is constantly endangered by the conflicting interests of all others, peace, at any price, becomes preferable to it. Peace, however, is the result of society alone; i.e. as defined by Hobbes, of the existence within a community of a sufficient force to control all individual wills and forces. But this is only practicable in two ways: either all are seized with a desire to terminate the state of hostility, and enter into a mutual compact, by which they engage to do no violence, nor to suffer it to be done to each other; or a single person succeeds by stratagem or force in establishing his own authority over the rest. The latter form of society is as legitimate as the former; and indeed, as the end of the institution is the

suppression of warfare among its members, and as the more unlimited the power is the better calculated it must be to effect this object, an absolute monarchy is the very best polity that can be devised. Against the government in such a society, it is evident that subjects cannot consistently possess any rights; for these would impede its effectiveness: they have but one simple duty, and that is—implicit obedience. (*On Human Nature; Leviathan, &c.*)

Bentham (born 1748, died 1832) sets out from Hobbes' principle, that every object would be perfectly indifferent but for its fitness to produce pleasure or pain, which, he declares, are the sole motives of human determinations. This proposition he does not attempt to prove, but, asserting that it is one of those primary and self-evident truths which are the foundation of all reasoning, he proceeds to draw from it certain practical conclusions in the form of definitions. Thus he defines utility to be the fitness of actions and things to augment the happiness, or to diminish the misery, of individuals and communities; and maintains that this is the only true and intelligible interpretation of what is usually called the lawfulness, goodness, justice, and morality of an action. The principle of utility is next defined to be that which exclusively derives the quality of actions from their twofold property of augmenting the happiness or misery of one or many. This, he asserts, is the only valid principle of moral appreciation; and he reduces all opposing theories to two classes, which he designates by the principle of asceticism, and the principle of sympathy and antipathy. Under the latter head, Bentham comprises every theory of morals which draws the distinction of good and evil from any other principle than a consideration of consequences; whereas he explains the ascetical principle as agreeing with the utilitarian in drawing its qualification of objects from their tendency to produce pleasure or pain, but as differing from it in that it proceeds in an inverse manner, and calls pain good, but pleasure an evil. To forego the least pleasure, simply as pleasure, is to act on a principle of asceticism; but the true disciple of utility holds every pleasure to be in itself good. Even the abominable pleasure which the criminal enjoys in gloating over his crime is good, so far as it is a pleasure; it is only evil so far forth as it entails the ill consequences of fear and punishment, which far transcend its guilty enjoyment. The practical conclusion, therefore, of the theory of utility is, that an action is only really good when it will give rise to more of pleasure than of pain; and evil, when its painful consequences exceed its pleasurable results. It becomes, therefore, of the first importance to possess an accurate standard by which the amount of pleasure and pain likely to result from certain actions, and the relative value of the two quantities, may be measured. This desideratum Bentham has attempted to supply in a manner that constitutes the most original and characteristic feature of his theory

and system. The first item of this moral arithmetic is what is intended for an exhaustive enumeration of all the pleasures and pains of which human nature is susceptible: in the next, he proceeds to furnish a method of determining their comparative value. For this purpose it is necessary to take into the account the following considerations: I. What are the intrinsic circumstances of the pleasure itself which can augment or diminish its value: and these are, 1. intensity; 2. duration; 3. certainty; 4. proximity, or remoteness; 5. fecundity, or the probability of its immediate pleasures engendering others more remote; 6. purity, or whether its pleasures are mixed or not with more or less of pain. II. What circumstances are likely to affect the sensibility of the agents, and so to modify indirectly the result. These are of two kinds, individual and general: to the former belong temperament, constitution, habits, intellectual development, and other traits of personal character: those of the latter order are little more than generalisations of the first, and are—sex, age, education, profession, climate, national character, government, and religion. III. What are the consequences which, going beyond the immediate objects of the action, remotely affect others more or less numerous, and even the whole of society. By allowing their due weight to all these particulars, Bentham pretends that any ordinary capacity may form a correct estimate of the real tendency of actions, and thereby arrive at that general utility which it is the proper end of morality to secure. (*Treatise on Morals and Legislation.*)

The recognition of a principle of action independent of self-love will afford a general characteristic of the remaining theories. Some of these, however, place the origin of the disinterested determination in a perception of moral good and evil by the intellect or reason; while others explain the distinction by certain facts which take place within the sensibility or emotive part of man, so that the disinterested determinations which result proceed from an instinct or sentiment. These two classes may be conveniently designated the *rational* and the *sentimental* or *instinctive*. Of instinctive theories, however, while some are content with referring the moral principle to an original and admitted tendency of human nature, such as sympathy or benevolence, others have de-
 it from a new and peculiar faculty.

To begin with the former class. According to Adam Smith (born 1723, died 1790), when we are in the company of another who is sensibly affected with any sentiment or passion, our nature spontaneously, and without the intervention of reason or will, tends to reproduce in ourselves the same sentiment or passion: and not only have we this disposition to sympathy, but we even feel a pleasure in finding ourselves brought thereby into harmony with those around us. Indeed, so strong and so instinctive is the desire for such union between our own minds and those of others, that when we are under any strong emotions in the presence

of another who is unable to conceive anything that approaches to the same degree of violence with our own, in such a case we involuntarily and unconsciously lower our passion to that pitch in which the spectator can go along with it. The spectator, on the other hand, seeing what we suffer, endeavours to enter into our sentiments, and rises by an instinctive complaisance to the level of them. In regard to those objects which have no peculiar relation either to ourselves or others, this sympathy is simple. In whatever degree, for instance, the love of truth may be felt; it will not directly affect the happiness of anyone; it cannot excite any feeling but a simple emotion of sympathy. It may, therefore, be allowed to appear as it is felt, because there is no reason either of instinct or of reason to suppress it. There are, however, certain internal dispositions which excite a twofold or even a triple sympathy, which are all of the same kind; thus, when we see a man animated with sentiments of charity and love, pity and benevolence, towards his fellow-men, we are affected by a twofold sympathy, *directly* with the benevolent disposition, and *indirectly* with the gratitude which is due from its objects. As, then, the two mutually strengthen each other, the benevolent dispositions evidently awaken the highest degrees of sympathy, and consequently they contribute most of all to effect that perfect harmony of sentiments and affections to which all men instinctively aspire. But, on the other hand, there is a divided sympathy. Suppose the case of merited anger; on the one hand we sympathise with the passion of anger, and on the other with the object of it, and with the sufferings which it may bring upon him. These are the elements of moral approbation and disapprobation. We approve those sentiments of others in which we ourselves are able to participate; and when this sympathy is pure our approbation is unqualified, but mixed with disapprobation when our sympathy is divided. But further, when we witness, for instance, an act of benevolence, we sympathise not only with the feelings of the actor, but also with the emotion of the party benefited. Now this emotion is gratitude; but what else is gratitude but an instinctive desire to do good to the benefactor? Consequently, as we participate in the feelings of the obliged party, we wish to do good to the author of the obligation; we feel that he *merits* it in reward for the good which he has done. As to the judgment which we pass on our own sentiments and actions, Adam Smith asserts that if it were possible for a human creature to grow up to manhood in some solitary place without communication with his species, he could no more think of his own character, of the propriety or demerit of his own actions, of the beauty or deformity of his own mind, than of the beauty or deformity of his own face. Since society is essential to sympathy, which is the rule of qualification of all our acts, the solitary cannot arrive at a consciousness of that

ETHICS

rule, and by it appreciate the morality or immorality of his acts. Our moral criticisms are first exercised upon the character and conduct of others, but we soon learn that others are exercising their judgment upon our own: we become anxious to know how far we deserve their censure and applause; and, in order to examine in this respect our own passions and conduct, we have the faculty of supposing ourselves spectators of our own dispositions and behaviour, and so experience in some degree the sensations which would be excited in our minds by the sight of similar actions and feelings in another. By virtue of this faculty we feel as it were a sympathy with ourselves when we have acted well, and are led to suppose that all other spectators will be similarly affected. This consciousness of union between our own conduct and the sentiments of our fellows constitutes the pleasure of rectitude. And further, by aid of the same principle by which we judge of the actions of others, we feel that we have a right to pronounce our own also to be good. This is a source of inward tranquillity and satisfaction, while the least suspicion of the contrary gives rise to the pains of remorse. In manhood, indeed, when experience has drawn a system of general rules from the occasional judgments of sympathy, and established them in the mind, a new source of pleasure arises. We have now an intellectual perception also of the conformity of the act with the law of morality; and independently of the instinctive approbation, the reason also awards to it its sanction. This rational perception is wanting in the infantine and uncultivated mind; but it is invariably found wherever education or experience has stored the mind with the general maxims of morality which are primarily founded on the instinctive emotions. The act of reason in approbation is simply a perception of the agreeableness of the act with the moral laws, and therefore implies them. Lastly, the act itself appears by its very nature to be part of a system of conduct fitted to establish a perfect agreement of sentiments among mankind; and this universal harmony being eminently beautiful in itself, we judge, in virtue of this perception, the act in question to be not only good but even beautiful. This is the principle of moral beauty, which is the origin of every other species of the beautiful. (*Theory of Moral Sentiments.*)

The doctrine of a moral sense owes its origin to Lord Shaftesbury (born 1671, died 1713). According to this writer, the human dispositions are of two kinds—the social or benevolent, and the personal or selfish. The former lead us to desire the welfare of others simply for its own sake and without regard to our own interests. In the developments of these affections the soul takes part, and some are naturally agreeable and others disagreeable to it; of the former it approves, while it disapproves the latter. As, then, these dispositions are a source of pleasure to the soul, there must be in it some

faculty distinct from the dispositions themselves, by virtue of which they become agreeable or otherwise, and which performs the same office in their case as they do with respect to their immediate objects. This faculty Shaftesbury calls a sense which he characterises from its mode of operation as *reflex*, and from its object-matter as *moral*. The dispositions which this reflex sense approves or disapproves are morally good or evil: virtue consists in yielding to the former, but resisting the latter. Between goodness and virtue there is agreement, but not identity; the former being merely a constitutional predominance of the benevolent affections in the character and conduct, the latter being the same state produced by the operation of the conscience or moral sense, which, when the personal affections are of equal force with the social ones, interposes its authority, and inclines the balance in favour of the latter.

Butler (born 1692, died 1752) in the same manner divides the principles of action into those which lead directly to private good, and those which promote immediately the good of the community. 'There are,' he says, 'as real and the same kind of indications in human nature, that we were made for society and to do good to our fellow-creatures, as that we were intended to take care of our own life and health and private good, and that the same objections lie against one of these assertions as against the other.' At the same time, he shows that the several passions and affections, which are distinct both from benevolence and self-love, do in general contribute and lead us to public good as really as to private. The promotion of the latter is the proper end of self-love; but self-love is by Butler carefully distinguished from selfishness, which consists in the weakness of the public affections and the undue strength of personal desires. Self-love, or an enlightened regard to our general happiness and highest ultimate interest, is not a vice, and is generally not nearly as strong in men as it ought to be; but selfishness is utterly at variance with the happiness of him who harbours it, since without the gratification of the benevolent feelings it is impossible to attain to the greatest satisfaction of our nature, of which they are a part. But, besides these personal and social instincts and self-love, Butler discovers in man another faculty, which by its very nature is supreme over all others, and authoritatively approves or disapproves both the affections of our minds and the actions of our lives. This principle is conscience. Its perceptions are immediate, and its very idea implies that supremacy and authority are essential to it. The nature of man is thus a complex constitution, and we cannot determine the final cause of his being unless we have a due knowledge of the component parts in their relation among themselves and to the end which they are designed to serve. 'Every work,' he argues, 'both of nature and art, is a system; and as every par-

ticular thing, both natural and artificial, is for some use or purpose out of and beyond itself, one may add, to what has been already brought into the idea of a system, its conduciveness to this one or more ends. Let us instance a watch: Suppose the several parts of it taken to pieces, and placed apart from each other; let a man have ever so exact a notion of these several parts, unless he considers the respects and relations which they have to each other, he will not have anything like the idea of a watch. Suppose these several parts brought together and united anyhow: neither will he yet, be the union ever so close, have an idea which will bear any resemblance to that of a watch. But let him view those several parts put together, or consider them as to be put together in the manner of a watch; let him form a notion of the relations which those several parts have to each other—all conducive in their respective ways to this purpose, showing the hour of the day; and then he has the idea of a watch. Thus it is with regard to the inward frame of man. Appetites, passions, affections, and the principle of reflection, considered merely as the several parts of our inward nature, *do not at all give us the idea of the system or constitution of this nature; because the constitution is formed by somewhat not yet taken into consideration, namely, by the relations which these several parts have to each other.* Bishop Butler goes on to remark, that 'what in fact or event commonly happens is nothing to this question;' for, 'one may determine what course of action the economy of man's nature requires, without so much as knowing in what degrees of strength the several principles prevail, or which of them have actually the greatest influence.' But between a machine and a man, he remarks, in reference to the illustration from the watch, 'there is a difference too important ever to be omitted. A machine is inanimate and passive; but we are agents. Our constitution is put in our own power. We are charged with it; and therefore are accountable for any disorder or violation of it.'

The first object of Hutcheson (born 1694, died 1747) is to show that the very frame of our nature which determines us to pursue happiness for ourselves, also determines us both to esteem and to benevolence on their proper occasions. Besides these original desires, he shows that there arise, in consequence of them, *secondary* desires of everything useful to gratify the primary ones. But there is also in man an idea of moral good which can be explained by neither of the former. By a careful analysis, Hutcheson shows that by moral good we understand neither what gives pleasure by satisfying our benevolence, nor what is simply good to others; nor is it what is useful to others or agreeable to the spectators; nor, lastly, is it a conformity to the will of God, or to law, or truth, or order: it is simply what the word itself expresses, which is simple and original and inexplicable by any other. From this originality and simplicity of the term,

Hutcheson argues that it must be perceived by a sense, because the senses alone are percipient of simple qualities; and by a special sense, since the quality apprehended by it differs from all other objects of sensation. Further, he observes that this perception is attended with pleasure, which is the property of all sensuous perceptions; and that as moral good is an end and motive of action, it must be apprehended by a sense, since the understanding can neither propose the ends of human activity nor exercise any influence on the will. Again, the pleasure which accompanies the perception of good, being a consequence of the discovered quality, necessarily presupposes it; therefore it is impossible to resolve moral good, or the approbation which we award to it, into that pleasure; this would be to resolve the cause into the effect, and the consequence into the principle. As the qualities which it is the province of the moral sense to discover belong to the internal affections and emotions, it is internal, and not external, although, like the outward senses, it is capable of improvement by education and habit. This sense is designed to govern all the others, and we have an immediate consciousness of its authority. Reason is the servant of this sense, its only office being to discover and to combine the means necessary to the attainment of the objects which the moral sense approves of. The object of this approbation is benevolence alone: every action, therefore, which has in view our own advantage may be innocent, but cannot be virtuous. (*Inquiry into Beauty and Virtue.*)

According to Hume (born 1711, died 1776), all the mental qualities and actions which are generally approved of by mankind agree in the circumstance of being useful to society. The fact that the different degrees of moral approbation correspond to the degrees of utility, affords an explanation of the greater merit ascribed to the benevolent passions: for these tend to the happiness of many, and indeed of all; whereas the personal affections tend to that of the agent alone. Yet even the latter are in a degree meritorious, inasmuch as they are useful to one, and they are only to be blamed when they are entertained at the sacrifice of the social feelings. The pursuit of self-interest is in the latter case culpable, although in itself it is not only innocent, but praiseworthy: for we admire in any character certain qualities, such as prudence, for instance, merely because they appear fitted to promote a man's personal welfare. In short, whatever is useful is morally good, and is only to be disapproved when it is preferred to what is more useful. That which judges of utility and the contrary is reason; but if we approve of one and disapprove of the other, and call the former good, but the latter evil, this is in virtue of a primary sentiment of our nature, which leads us to prefer the useful to the hurtful, as we prefer what is sweet to what is bitter. This instinct, however, is distinct from and frequently opposed to self-love; for this

ETHICS

would lead us to love what is useful to ourselves, and not what is useful in itself absolutely and independently of any reference to our own advantage. This instinct is commonly called *conscience*, or the moral faculty, but more frequently designated by Hume as *benevolence* or *humanity*, inasmuch as its object is the good of mankind generally. As to the idea of moral obligation, it is simply a conception of the understanding. What is honoured by this name is, he says, nothing more than the undoubtedly correct view, that there is more happiness in obeying the impulses of the moral sense than in following the dictates of self-love. The reason is incapable of exercising any influence on the will. What determines us when we resolve to act rightly is merely the charm which utility exercises on the mind, and the force of certain dispositions which propel us to seek the good of ourselves and others, and are invariably seconding the promptings of conscience. (*Inquiry concerning the Principles of Morals*.)

Mackintosh (born 1766, died 1832) agrees with all the writers of the distinctive school in denying conscience to be either a state or act of the understanding; but he differs from one form of the sentimental theory by denying that man has any special organisation for moral perception, while he equally dissents from the other view, which would refer these perceptions to some one of the original and admitted sentiments of our nature. Butler and Stewart had shown that self-love is a secondary principle; and Hartley had exhibited the important part which association plays in the formation of our passions and affections, and even of our sentiment of virtue and duty. This view was further developed by Mackintosh, who declared conscience itself to be a similar derivative. In the same manner he says that in the formation of self-love the desire which originally attaches to external objects is transferred to the pleasure which results from their attainment; so in the case of conscience the agreeable and disagreeable sensations which belong naturally to certain actions are transferred to the volitions which determine conduct, so that the latter become at last the immediate objects of love and repugnance. In this manner there is formed by association a number of secondary desires and aversions, whose proper object is volition, and which collectively form that interior principle called *conscience*, which judges, without regard to consequences, unerringly and authoritatively. As to the action of conscience on the will, this is composed both of the peculiar energy of the primary dispositions, which it causes to triumph, and of the pleasures naturally attached to them, as well as those which are produced by the gratification of the secondary affections. Accordingly, Mackintosh strongly insists upon the distinction between perception and emotion, and declares that the phrase *association of ideas*, as overlooking this distinction, conveys but a partial and incomplete view of the truth. He therefore proposes to substitute for it asso-

ciation of thoughts with emotions and with each other, but at the same time declares that the term *association* very inadequately indicates that perfect combination and fusion which occurs in these operations of the mind. For the moral faculty is properly and intelligibly spoken of as one. Now it is as common in mind as in matter for a compound to have properties not to be found in any of its constituent parts: the originally separate feelings are so completely blended together that they can no longer be disjoined from each other. Thus the sentiment of moral approbation, formed by association out of antecedent affections, may become so perfectly independent of them that we are no longer conscious of the process by which they were formed. It is in this mature and sound state of nature that our emotions at sight of right and wrong are ascribed to conscience. And although this supreme arbiter and judge of human conduct does not supersede the ordinary motives of virtuous feelings and habits, which are the ordinary motives to good actions, it yet exercises a lawful authority over them. Whatsoever actions and dispositions are approved by conscience acquire the names of virtues and duties; they are thereby pronounced to deserve commendation, and we are justly considered as under a moral obligation to practise the actions and cultivate the dispositions. The peculiar character of the moral sentiments is their exclusive reference to *states of the will*, and this is a character both of the private desires and social affections, and indeed, among the many dissimilar elements that enter into the formation of conscience, this is the only common property that the mind can discover. Hence, however, the facility with which general terms, at first limited to relations between ourselves and others, are gradually applied to any voluntary acts and dispositions: it is thus that prudence and temperance, for instance, become objects of moral approbation. On the other hand, as the will is the sole means of gratifying any passion, the power of conscience is co-extensive with the whole man. It is a universal principle, because will is the universal means. And as, when the mind is in a healthy state, nothing is interposed between it and the will, the dictate of conscience is immediately followed by a determination of will; conscience is thus at once universal, independent, and commanding. Lastly, as Mackintosh held that utility, as tending to promote the greatest happiness of the species, is the criterion of morality, he naturally felt himself called upon to explain the fact, that, while the moral approbation involves no perception of a beneficent tendency, there is nevertheless a striking coincidence between that principle and the moral sentiments. He replies that it is true that conscience itself rarely contemplates so distant an object as the welfare of all sentient beings, but that all its elements are invariably tending to this end. The social affections promote happiness so far as their foresight and power extend; the rules of justice are conducive, if not necessary, to the

ETHICS

well-being of society; even the angry passions, so far as they are ministers of morality, are employed in removing hindrances to the welfare of ourselves and others; and if the private passions terminate in the happiness of the individual, this is yet a part of the general happiness. And although this beneficent tendency be not one of the natural objects of conscience, because our voluntary acts are not felt to affect it, yet little is left to reason to perform; which is, to discover merely the truth, that the acts of those who labour to promote separate portions of happiness must increase the amount of the whole. (*Dissertation on the Progress of Ethical Philosophy.*)

The distinctive characteristic of the rational theory of morality is, that it considers the idea of good to be an *a priori* conception of reason, in which the idea of obligation is necessarily and essentially implied. As to the nature of the idea itself, two opinions have been held. While some moralists of this school pronounce it to be simple and immediate, others resolve it into some higher notion of the intellect, from which it derives at once its explanation and authority.

The most distinguished representatives of the latter opinion are Clarke and Wollaston; while the former has found able advocates in Cudworth, Price and Stewart.

According to Clarke (born 1676, died 1729), the universe is an assemblage of objects held together by certain mutual relations which result from their respective natures; but as the nature or essence of things is immutable and real, and the essence is the principle of the relations, the latter must be equally real and immutable; and as they must have been always present to the Eternal Mind, they are also eternal. Now, as soon as reason conceives these relations as constituting the laws of individual things and the order of the universe, they immediately appear to command the respect of every free and rational agent. Hence the obligation on every creature capable of thought to act conformably to those relations; and every act agreeable to them is judged to be good, and evil if opposed to them. Now, moral good being the conformity to the relations of objects, these, while they constitute, serve also to explain, all duties. Thus, the true nature of God and man, and their reciprocal relations, being known, the duties of man towards God are at once discoverable. In the same way, the duties of man to his fellows similarly suggest themselves from a consideration of their relations as equally free and independent beings; and as the latter relation is one of equality, whereas that between God and man is one of inequality, the difference between the two classes of duties which those relations respectively engender is at once conceivable. In confirmation of this view of the moral principle, Clarke appeals to the historical fact of the gradual development of moral ideas among mankind: for the knowledge of the nature of things, and their consequent rela-

tions, is neither natural nor immediate to the mind, but is gradually unfolded by observation and science, which are more or less complete according to the degrees of its culture. The evolution of moral science, although subsequent to that of nature, nevertheless, being once awakened, is promoted by its progress, and keeps pace with the advancement of civilisation. (*Being and Attributes of God; Evidence of Natural and Revealed Religion.*)

Wollaston (born 1669, died 1724) makes morality to be conformity to truth. In support of this view he asserts that actions, like words, are but signs, and that consequently every true proposition, i.e. one which expresses things as they are, may be contradicted by deeds as well as by words. To violate a compact, for instance, is simply to deny by that act that there is any such compact subsisting. He then asserts that no act, whether word or deed, of any free and rational agent to whom moral good and evil are imputable, which interferes with any true proposition, or denies anything to be as it is, can be right. For, 1. If a false proposition be wrong, the act which implies, or is founded on it, cannot be right. 2. Whatever interferes with a true proposition, which expresses the relation between the subject and attribute as it is in nature, must, therefore, interfere with nature, and is consequently unnatural, or wrong. 3. An act which contradicts a true proposition contradicts what is, and is therefore a revolt against God, the author of whatever is. 4. To deny things to be as they are, is a transgression of the great law of our nature—the law of reason. What is said of acts inconsistent with truth may be said of omissions to act, since by these, also, true propositions may be denied to be true. For instance, whoever having engaged to do some certain act, nevertheless voluntarily omits to do it, behaves himself as if there had been no such promise or engagement. Having thus established his theory, he proceeds, like Clarke, to show that it is agreeable to facts, and especially with that of the progressive development of morality. For morality, being simply the truth expressed in action, implies the knowledge of truth; and consequently the improvement of the moral perceptions must be proportional to the progress of science. It also affords an explanation of erroneous views in morality, and of the difference so universally drawn by the common sense of mankind between error and vice. If it is possible to err in morals, this is because the mind is liable to err in science, and not to see things as they actually are. To err in morals is but to affirm practically a false position: hence the act may be evil, but the agent is not culpable, since his error is involuntary. Lastly, Wollaston maintains that his theory, far from being inconsistent with the acknowledged characteristics of the idea of moral good, affords the only just explanation of them. The truth is immutable, because it expresses the unchangeable nature

of things, and therefore the ideas of moral good are immutable. Hence, too, the same eternal distinction between moral good and evil as between truth and falsehood. Whatever, in short, may be predicated of truth, is applicable to the moral principle; and its foundations are as valid and imperishable as those of science itself. (*The Religion of Nature.*)

The other form of the rational theory, which explains the idea of good to be an immediate conception of the intuitive reason, intelligible in itself, and incapable of definition, now remains for elucidation. According to Cudworth (born 1617, died 1688), certain universal and absolute ideas exist from all eternity in the divine mind; the human intellect, therefore, as emanating from the divine mind, by its nature possesses these ideas antecedently to experience. They remain dormant, it is true, until outward objects call them forth; but when once awakened, they immediately apply themselves to things, and give them a significant character, which in themselves they do not possess. Cudworth's chief object in advancing this theory was to exempt the ideas of right and wrong from the arbitrary and relative character with which the sensuous doctrines of Hobbes had invested them. Accordingly, he shows that no relation of human will or pleasure can constitute these ideas. Positive laws, he urges, do not oblige by their mere enactment, but by virtue of the natural ideas of justice and obligation which they imply. Neither is this idea the mere creature of man's reason, for reason does but conceive the idea, and, by applying its unchangeable standard to actions and characters, appreciates and judges them. Lastly, this idea is simple and undefinable, and inseparably combined with that of obligation. Hence every virtue assumes the character of a duty, and is as unalterable as good itself. (*Eternal and Immutable Morality.*)

Price (born 1723, died 1791) ascribes all simple ideas to two faculties—sense and understanding. The latter sees things as they are; the former perceives only the effects which they produce on the sensuous organisation. The ideas of the understanding consequently express realities which are independent of man, whereas those of the sense are feelings which would be different if man's sensuous organs were changed. Now the question of the objective reality and immutability of the ideas of right and wrong reduces itself to the enquiry into their origin. According to Price, they belong to the understanding as a faculty of intuition or immediate power of perception, distinct from the understanding as a reasoning or deductive faculty. The doctrine which would assign them to sensation as their origin has its source in the fact that the moral perceptions are invariably attended with agreeable or disagreeable emotions, and in the exclusive consideration of this circumstance. But when men declare gratitude to be a virtue, and ingratitude a vice, they intend to signify not merely that they produce emotions in their own minds, but that

they are naturally virtuous and vicious in themselves. If by virtue and vice nothing more be meant than certain mental affections, then, in that case, our moral judgments would be infallible, and the same act might with equal truth be the subject of the most conflicting estimates, and all things would be indifferent in their own nature, since the understanding, which alone apprehends things as they are, could see in them neither good nor evil. Moreover, in this case, they would be without authority; for what obligation can there be to do what is pleasing, or to forbear what is displeasing? But these ideas are both immutable and imperative: they are immutable, since they are real qualities of actions, and every real quality is a part of the nature of things, which is immutable. God may destroy the things themselves, but He cannot cause them to be what they are not. After establishing the rational origin and immutable character of the moral perceptions, Price proceeds to explain the manner in which they are apprehended by the intuitive reason. As any event suggests the idea that it must have taken place in time, and thereby we arrive at the idea of duration, in the same way certain actions of free and rational agents are immediately apprehended to be good or evil, and the ideas of right and wrong arise in the consciousness. As to the notions of moral beauty and deformity, these we ascribe to good and evil actions in virtue of the pleasure and pain which accompany, but yet are distinct from, the perception of right and wrong. In contemplating the actions and affections of moral agents, we have both a *perception of the understanding* and a *feeling of the heart*; the latter are the effects of the former, and partly depend on the positive constitution of our nature, and partly on the essential congruity of object and faculty. The former are wholly inexplicable, and the only account we can give of them is—such is our frame; so God has seen fit to make us. But there are some objects and ideas which have a natural fitness and unfitness to please our mind; and such is the nature of certain actions that when they are perceived by a rational being, there must result in him certain emotions and affections. These are at first of a purely intellectual kind; but, as such, they are too weak to govern and actuate man, and they are therefore combined with a stronger excitement, and we are endowed with certain special instincts which impel us to goodness, and by means of these we are effectually moved towards their proper objects. As to duty or obligation: this idea is so intimately allied to that of good, that one cannot appear without the other. It is not plainer that figure implies something figured, than that rightness implies oughtness. Rewards and punishments suppose in their very idea moral obligation, and are founded upon it. They do not make it, but enforce it, or furnish additional motives to comply with it. They are the *sanctions* of virtue, but not its *efficient*s. The ideas of good and ill desert are equally immediate; for they

ETHICS

are really nothing less than a species of the ideas of right and wrong; although there is this difference in them, that while the latter are properly ascribed to actions, merit and demerit are applicable to agents or persons only. We have an immediate approbation of making the virtuous happy, and discouraging the vicious, apart from all consequences. The conception of virtue is totally distinct from the fact that virtue is a source of pleasure; for it is one thing to find by experience that the tendency of virtue is to the happiness of the world, and vice to its misery, and another to conceive that virtue is by a necessary truth deserving of happiness. Neither does it result from the view that virtue is of public utility; for, even though this consideration may incline us to wish good to the virtuous, yet are we antecedently moved to the same wish by the more immediate and more simple consideration that he is virtuous, and as such, without any other consideration, we pronounce him deserving of honour. Lastly, Price makes liberty and intelligence to be essentially necessary to the morality of the agent, and distinguishes absolute virtue, which is to act voluntarily and consciously in conformity with the moral laws, from practical virtue, or acting on a belief of good in supposed conformity to good. (*View of Principal Questions and Difficulties in Morals.*)

Stewart (born 1753, died 1828) distinguishes two questions in the fundamental problem of ethics—that of the nature of good, and that of the faculty which discerns and judges of it. With respect to the first, he teaches that upon observation of certain actions the idea of good arises in the mind. This idea represents a certain quality of the actions themselves, and inherent in them, like the primary qualities of bodies, and therefore independent of the sensuous percipient, and not, like the secondary qualities, mere relations between us and the actions. As to the nature of these qualities, they are, like the ideas which we have of them, perfectly original, simple, and irreducible, and consequently indefinable. He further shows, after Price, that it is impossible to explain the terms *good* and *evil* except by synonyms, or by substituting for the ideas which they represent some of the circumstances which accompany the perception of them. As to the second question, Stewart argues that good being a simple and real quality in actions, it is impossible to refer the idea of it to any faculty which is not a source of original ideas, and which does not apprehend the real and inherent qualities of objects. It is, therefore, impossible to refer it to a sense (such as that of taste or smell) which reveals, not the real nature of objects, but only the effect which they produce in the perceiving subject; nor to reason—if by this term we understand nothing more than the faculty which seizes the relations and deductions of ideas previously established, because the idea of good is simple and original, and not one of relation and consequence;

ETHYL CARBONIC ACID

but if by sense we understand a faculty analogous to that which perceives the primary qualities of bodies and their existence—or if by reason we mean the intuitive understanding which furnishes the simple, primary, and original ideas of time, space, and causation—then the ideas of good and evil may be referred to either. If Stewart inclines, nevertheless, to favour the claims of reason, he yet declares the question to be unimportant when once it has been admitted that good and evil are simple and indefinable. (*Philosophy of the Active and Moral Powers.*)

In this exposition, the first object has been to give a correct and impartial view of the several theories which have been proposed of the nature of virtue and of the moral perceptions. Their comparative merits are left to the judgment of the reader. (*Cf. Ritter, History of Ancient Philosophy; Mackintosh, Dissertation on Ethical Philosophy; Schleiermacher, Kritik der Ethik; Jouffroy, Droit Naturel; Cousin, Cours de Philosophie Morale; Bain, The Senses and the Intellect, The Emotions and the Will.*) [SCHILLING, PHILOSOPHY OF.]

Ethionic Acid. May be viewed as the bisulphate of the diatomic radical ethylene. It is ethylene united with two equivalents of water, and four of sulphuric acid.

Ethiopian Language. The Ethiopian language, properly so called, survives only in books. It belongs to the Semitic class of languages, bearing a close affinity to Arabic, but is written from left to right. The literature extant in this tongue is almost wholly biblical and ecclesiastical. The Old and New Testament was translated into Ethiopian from the Alexandrian text about the fourth century. The Ethiopic version of the apocryphal Book of Enoch [which see] was found during the last century by the African traveller Bruce.

Ethiops Mineral. The black powder obtained by rubbing mercury with sulphur.

Ethmoid (Gr. ἔθμως, a strainer, and εἶδος, form). The ethmoid or cribriform bone. A bone of the head enclosed in the *os frontis* between the orbital processes; it is very light and spongy, and consists of a network of convoluted plates.

Ethnography. [ANTHROPOLOGY.]

Ethnology. [ANTHROPOLOGY.]

Ethyl or Ethale. A name applied to the organic radical ($=C_2H_5$) contained in ether and alcohol. Ethyl is best obtained by the action of zinc upon iodide of ethyl. It is at ordinary temperatures a colourless and invisible gas, possessing a very slight ethereal odour and burning with a brilliant white flame. Its specific gravity is 2.0039. Exposed to a pressure of $2\frac{1}{2}$ atmospheres it condenses to a colourless and mobile liquid.

Ethylamine. A powerful, caustic, artificial organic base, volatile and liquid, and derived from ammonia by replacement of three equivalents of hydrogen by three of ethyl.

Ethylcarbonic Acid. [CARBETHYLEN ACID.]

ETHYLENE

Ethylene. [OLEFANT GAS.]

Etiolation. That condition of a plant in which all the green colour is absent. Such a state is produced by want of light. When it is artificially obtained by keeping plants in the dark in order to insure their being more tender and insipid than is natural to them, it is called *blanching*, as in the case of celery. Etiolated parts become green by exposure to light.

Etiquette (Fr. *a ticket*). The ceremonial code of polite life, more voluminous and minute in each portion of society according to its rank. The word is derived from the custom of arranging places at processions, &c. by tickets delivered beforehand to applicants. The Byzantine court appears to have carried the practice of ceremonial observances to the greatest extent. But of modern courtly etiquette, Philip the Good, duke of Burgundy, is regarded by some as the founder. At no time, probably, was the spirit of etiquette so predominant and so tyrannical as in the court of Louis XIV. (*Memoirs of Saint Simon*.) The smaller courts of Germany caricatured the ceremonial of that of the Great Monarch, and carried its strictness to an absurd extent. At the present day the ancient etiquette of courts is continually losing something of its strictness.

Etolle (Fr. *a star*). In Heraldry, a star which differs from a mullet in its number of points, and four of the points being rayant.

Etruscan Language. The language of the people of ancient Etruria. Its philological place has not yet been determined. It has been assigned by some to the Celtic class of languages; but even the affinity of the Etruscans with the Celtic tribes cannot be positively maintained. The Etruscan was read from right to left.

Etymologicum Magnum. A valuable vocabulary of the Greek language, by an unknown author. It contains many traditions respecting old or uncommon words. Sylburg's edition (1894) has a good index; the edition of Schäfer (Lipsz. 1816) is a reprint of that of Sylburg. Sturz also edited an edition, Lipsz. 1818, 4to.

Etymology (Gr. *ἐτυμολογία*, from *ἔτυμος*, true). The science which treats of the origin or root of individual words, and of the relation borne respectively by their several meanings to that origin. It is a branch of the general science of philology. [PHILOLOGY.]

Eucalyptus (Gr. *εὖ*, well, and *καλύπτω*, to cover). This genus of *Myrtaceæ* furnishes the gigantic Gum-trees and Stringy Barks of the Australian and Tasmanian forests. These trees are sometimes of enormous size, and the timber is of excellent quality. *E. gigantea*, the Stringy Bark, has been known to yield specimens upwards of 300 feet high, and 100 feet in girth at a yard from the ground. The Blue Gum, *E. globulus*, however, yields the most valuable timber, which is much used by ship-builders, millwrights, &c., and by engineers in the construction of works requiring beams of

EUDIOMETER

great size. *E. resinifera*, and other species, yield a red astringent gum, resembling kino; *E. piperita*, an essential oil; and *E. Gunnii*, the Tasmanian Cider-tree, a cool refreshing liquid upon incision of the bark in spring.

Eucharist (Gr. *εὐχαριστία*). A term signifying properly *giving of thanks*, but generally used in theological language to denote the sacrament of the Lord's Supper. The celebration of this rite is derived from the account given by the Evangelists of the action of our Lord in offering to the apostles bread and wine, adding at the same time, 'Do this, as oft as ye shall do it, in remembrance of Me.' This commemoration is spoken of in the New Testament, and by the Fathers, as a sacrament and a mystery. For the solution which the Roman Catholics give for this mystery, see TRANSUBSTANTIATION; and for that of the Lutherans, see CONSUBSTANTIATION.

According to the doctrine of the Anglican church, an inward and spiritual grace is conveyed in the Eucharist to those who partake of it; but many Protestant bodies conceive the communion to be nothing more than an outward act of obedience enjoined as a commemorative ceremony, and only instrumental to salvation in the same way as any other act of obedience. [SACRAMENT.]

Euchlorine (Gr. *εὐχλωρος*, bright green). A name given by Sir H. Davy to the oxide of chlorine, in consequence of its deep yellow-green colour.

Euchology (Gr. *εὐχολόγιον*). A book of prayers; synonymous, in the phraseology of the Roman Catholic church, with *missal* or *breviary*.

Euchroic Acid (Gr. *εὐχροος*, of a fine colour). One of the products of the destructive distillation of mellitate of ammonia. It is crystalline, and gives a beautiful blue colour (*euchrone*) when placed in contact with zinc.

Euchysiderite (made up from Gr. *εὖ*, well; *χίμα*, I fuse; *σίδηρος*, iron). A silicate of lime, magnesia, and protoxide of iron. A species of *pyroxene*.

Eucrase (Gr. *εὖ*, well, and *κλάω*, I break). A silicate of alumina and glucina, found in small greenish crystals, in Peru and Brazil, and in auriferous sands, near the river Sanarka, in the South Ural. Though well suited for jewellery, on account of its great hardness, and the fine polish which may be given to it, this stone is seldom used as a gem in consequence of its rarity and fragility.

Eucrasia (Gr. *εὐκρασία*). A well proportioned mixture of qualities, by which a body is said to be in good order, and disposed for a good state of health.

Eudialite (Gr. *εὐδιδαντος*, easily dissolved; from the facility with which it is dissolved in hydrochloric acid). A silicate of zirconia, lime, and soda, with the oxides of iron and manganese, found on the west coast of Greenland.

Eudiometer (Gr. *εὐδία*, calm air, and *μέτρον*, measure). This term is generally applied to instruments used for the analysis of atmospheric air and other gases. [GASOMETRIC ANALYSIS.]

EUERGETES

Euergetes (Gr. *a benefactor*). A title of honour frequently bestowed by the Greeks on those who had served the state well, and given more especially to some of the Egyptian Ptolemies. Reference is made to this practice in St. Luke xxii. 26.

Eugenia (in honour of Prince Eugene of Savoy, an eminent patron of botany). A genus of *Myrtaceae*, consisting of tropical American or West Indian trees and shrubs, the most important of which is the *E. Pimenta*, the unripe sun-dried fruits of which are Allspice. This tree is much cultivated in the West Indies. *E. cauliflora* furnishes the Jabuticaba fruits of Brazil; and *E. malaccensis* and *E. Jambos*, the famous Rose-apples of the East.

Eugénine. A crystalline substance extracted by alcohol from cloves.

Eugubine Tablets. By this name are known certain bronze tablets, found in 1444 near the ancient Eugubium, now Gubbio. Of the inscriptions, five are in Umbrian and Etruscan character, the two others being in Latin. In the opinion of Sir G. C. Lewis, no attempts to interpret them have been successful; but Professor F. W. Newman seems to have traced clearly the connection of many of the Umbrian words with their Latin forms.

Eukairite (Gr. *εὐκαιρος, opportune*). A selenide of silver and copper. This rare mineral has been met with only at the copper mine of Skrickerum in Norway, and lately in Chili in the Cordilleras of Copiapo and at the mines of Flamenco north of Tres-Puntos. Berzelius, by whom it was originally discovered and analysed, gave it the name of Eukairite in allusion to his discovery soon after the completion of his examination of selenium.

Eulabes (Gr. *εὐλαβής, cautious*). A genus of Passerine birds, belonging to the family of thrushes, and distinguished by having broad strips of naked skin on each side of the occiput, and a bald spot on the cheek. The bill nearly resembles that of a thrush; their nostrils are round and smooth. The species are termed *Mainates* by the French ornithologists; and the Javan *mainate* (*Eulabes javanensis*) of all birds is said to imitate most completely the language of man.

Eulerian Integrals. The name given by Legendre in his *Exercices de Calcul Intégral*, vol. ii., to two important definite integrals, whose properties were first signalled by Euler in his *Institutiones*. The first Eulerian integral is

$$\int_0^1 x^{m-1} (1-x)^{n-1} dx,$$

for which Binet has proposed the symbol $B(m, n)$ or $B(n, m)$, since by substituting $1-x$ for x it may be easily shown that the above integral is equal to

$$\int_0^1 x^{n-1} (1-x)^{m-1} dx.$$

The second Eulerian integral is

$$\int_0^\infty e^{-x} x^{n-1} dx,$$

EUNUCH

an equivalent form of which is

$$\int_0^1 \left(\log \frac{1}{y} \right)^{n-1} dy.$$

The symbol proposed by Legendre, and now generally used, for this second transcendental is $\Gamma(n)$, on which account it is frequently called the GAMMA-FUNCTION [see the term]. The two Eulerian integrals are connected by the relation

$$B(m, n) = \frac{\Gamma(m) \cdot \Gamma(n)}{\Gamma(m+n)}.$$

Of this and of other properties of Eulerian integrals, demonstrations will be found in any good treatise on the Calculus.

Eulima. A genus of marine shell-clad Gastropods, whose characters are *shell* turreted, acuminate, with many whorls; aperture ovate, acuminate posteriorly; outer lip thickened, and bearing numerous obsolete *varices* or wart-like processes; operculum horny, thin, and with its nucleus anterior.

Eulogy (Gr. *εὐλογία, praise*). In a general sense, an encomium pronounced on any person; but, in a more restricted meaning, it was used in Ecclesiastical History to denote any present bestowed on the church after having been *blest* or *hallowed*.

Eulytine (Gr. *εὐλύτης, easily loosed*). A mineral found at Freiberg, composed of silica, oxide of bismuth, and alumina.

Eumenides (Gr.). In Greek Mythology, this name, significant only of gentleness, was given by euphemism to the Erinyes. [ERINYS.] By later poets the name was confined to the three sisters commonly known as the Furies, Allecto, Megæra, and Tisiphonê.

Eunice (Gr. *Εὐνίκη*, the name of a Nereid). A genus of marine Dorsibranchiate Anellidans, having tufted branchia, and a mouth armed with three pairs of horny jaws. One species (*Eunice gigantea*) attains the enormous length of between four and five feet.

Eunomia (Gr.). One of the small planets belonging to the group between Mars and Jupiter. It was discovered by M. de Gasparis at Naples on the 29th of July, 1851, and is the fifteenth in order of discovery. At its discovery it appeared like a star of the ninth magnitude.

Eunuch (Gr. *εὐνοῦχος*, literally *one who has the care of a bed-chamber*). A term applied to those who have been subjected to the operation of castration. This practice seems to have originated in the jealousy which prevails in Eastern countries. As far back as the time of Herodotus, it was carried to a great extent by the Persians, who not merely intrusted to eunuchs the care of their wives and daughters, but considered them in every respect as more trustworthy than others. In the middle ages the 'chief of the eunuchs' was one of the most important functionaries of Eastern government; and the seraglios of these countries are superintended by eunuchs even in the present day. In modern times the loss of virility is in some countries believed to preserve and improve

EUNYMUS

the voice; and hence, especially in Italy, this operation is or was practised upon children intended to supply the operas of Europe with singers. Zeal for religion has also caused many persons to undergo this operation. As early as the third century there arose a class of enthusiasts, who, animated by the example of Origen, not only castrated those of their own persuasion, but even all persons on whom they could lay their hands. Several of the Christian Roman emperors instituted severe prohibitions against this revolting practice; and at a later period the council of Nice excluded from the pale of the church all who, actuated by whatever motives, had allowed themselves to be thus mutilated.

Eunymus, sometimes written **Eponymus** (Gr. *εὐνυμος*, literally of *good name*, a euphemism for *hurtful* or *unlucky*). A genus of shrubs or small trees of the order *Celastraceae*, the common species of which, *E. europæus*, called Skewerwood or Prickwood, yields a strong compact easily-worked light yellow wood, applied to many useful purposes, and from which a kind of charcoal is made, much approved by artists. The foliage, flowers, and fruit are poisonous, though the last are sometimes used as a dye. The orange-coloured arillus disclosed by the bursting of the bright rose-coloured capsules gives the plant in autumn a very striking appearance.

Eupatorium (Gr. *εὐπατόριον*). The name in common use for a genus of *Compositæ*, one species of which, *E. perfoliatum*, is a valuable tonic stimulant, used as a substitute for Peruvian bark in the cure of intermittent fevers in the United States, where it is a native; *E. Ayapana* of South America is reputed to be a powerful sudorific. The name is sometimes given to the herb Agrimony (*Agrimonia Eupatoria*), in common use in Holland as an alterative.

Eupatrides (Gr. *εὐπατρίδης*). In Ancient History, the nobles of Attica, in whose hands in early times all the power of government was so vested that the lower orders sank into a state of degradation under the pressure of debt, which, if not paid, gave the creditor power over the bodies and liberties of the debtor and his family. These evils were remedied by the legislation of Solon, who reduced the interest of debts, and deprived the creditor of his power over the body of the debtor, while at the same time he threw the judicial and much of the legislative power into the hands of the people at large or *Demos* (*Δῆμος*). Later alterations in the constitution of Athens by degrees deprived the Eupatrides of all their political privileges, and finally established an unmixed democracy.

Eupepsia (Gr.). Good digestion. [*Dyspepsia*.]

Euphemism (Gr. *εὐφημismus*). A figure in Rhetoric, by which one expression is substituted for another, which conveys, through some association of ideas, an image offensive to the hearer or reader. But the euphemisms of the heathen

EUPHOTIDE

world generally spring from a desire of deprecating the wrath of malignant beings, by attributing to them characteristics opposite to those which really belong to them. Thus, the Furies were, by the Greeks, termed Eumenides, *gentle*, while the Black Sea was called Euxine, or the *hospitable*.

Euphony (Gr. *εὐφωία*, *goodness of voice* or *rhythm*). In contradistinction to Cacophony [which see]. That quality in language which results from happy combinations of the enunciative elements; such especially as, though essentially different in their characteristic powers, melt easily into each other, so as to preserve an uninterrupted flow without labour to the speaker or offence to the hearer.

Euphorbia (after Euphorbus, physician to Juba, king of Mauritania). A large and diverse family of acrid plants, typical of the *Euphorbiaceae*. They are milky plants, mostly herbaceous, sometimes shrubby, and not unfrequently succulent and leafless, and then having very much the aspect of *Cacti*. The most important product of the genus is *Euphorbium*, an acrid resinous drug, obtained from certain succulent species, as *E. officinarum*, *canariense*, and others. The roots of *E. Ipecacuanha*, *Pithyusa*, and *Gerardiana* are emetic. *E. Cathimandoo*, an Indian plant, furnishes a kind of Caoutchouc. Though generally acrid and more or less poisonous, some species are edible. Thus *E. edulis* forms a potherb, its acridity being dissipated by boiling.

Euphorbiaceae (Euphorbia, one of the genera). A very extensive natural order of diclinous Exogenous plants, found in almost all parts of the globe. Among the diclinous orders, they are known by their scattered flowers, their tricocous fruit, and their definite suspended anatropal ovules. Their sensible properties are, on the whole, poisonous and exciting, being both of a volatile nature and often dispelled by heat. Thus the stem of *Manihot utilisima* or *Cassava*, which, when raw, is poisonous, becomes a wholesome food when roasted. In the seeds the albumen is harmless, but the embryo is acrid. The seeds of *Ricinus communis*, which by pressure yields Castor Oil, and those of *Croton Tiglium* are purgative; as are the leaves of the Common Box, *Burus sempervirens*. The bark of several species of *Croton*, the wood of *C. Tiglium*, and of *Burus*, and the leaves of *Cicca disticha* and several *Euphorbias* are sudorific. The root of various Euphorbias, and the juice of *Commia*, *Mercurialis*, and others are emetic. Caoutchouc is abundantly furnished by *Siphonia laticia*; and the aromatic Cascarilla bark is the produce of *Croton Eleutheria*.

Euphorbium. An acrid gum resin, the produce of *Euphorbia officinarum* and other species; it is violently purgative and emetic, and the dust of it is dangerously stimulant to the nose.

Euphotide (Gr. *εὐ*, and *φῶς*, *light*). A rock consisting of felspar and diallage. It is the *gabbro* of the Italian artists.

EUPHRASIA

Euphrasia (Gr. *good cheer*). A genus of Scrophulariaceous plants, including the *E. officinalis* or Eyebright, which is a popular remedy for weak eyes, and is also an ingredient in British herb tobacco.

Euphrosyne. [CHARITIES.]

Euphuism. An affected style of speaking and writing, which became a fashion during the reign of Queen Elizabeth. The taste of an age which was gradually becoming conscious of the powers of the English language, tended to a love of affected conceits, which was carried to absurd lengths by John Lilly in his *Euphuus* (Gr. *graceful or witty*). The extravagant antitheses and illustrations of this worthless book were received with delight by critics who worshipped the 'curious invention' of the author. This style has been ridiculed by Shakespeare and Ben Jonson; but it should be remembered that Sir Walter Scott's imitations introduced into his romance *The Monastery* preserve little of its real character. (Hallam, *Literature of Europe*, part ii. ch. vii.)

Euphon (Gr. *very fat*). A very limpid liquid which stains paper like oil, and which exists in the tar produced during the destructive distillation of many animal and vegetable substances. Its specific gravity is 0.74, and it boils and evaporates at 340°. It is insoluble in water, but dissolves in ether and alcohol. It is insipid and inodorous, but highly inflammable.

Euphyron (Gr. εὐφύρον, *fire*). A term applied to several contrivances for obtaining instantaneous light; such as lucifer matches, &c.

Harite or White Stone (Gr. εἰρός, *broad*). A fine-grained granite, in which felspar predominates.

Harceydon (Gr. εἰρκάδων). A violent wind, mentioned in Acts xxvii. The name seems to signify a storm from the east; but the readings vary greatly, and among these variations occurs the term εὐκαίδων, in the Latin Vulgate, Euro-aquilo, the north-east wind.

Europa (Gr. Εὐρώπη). In Greek Mythology, the daughter of Agenor and Telephassa, and sister of Cadmus the founder of Thebes. According to some legends her birthplace was in Phœnicia. Thence she was carried away by Zeus or Jupiter in the form of a white bull, and became by him in Crete the mother of Minos, Rhadamanthus, and Æacus. ('Comparative Mythology,' in *Oxford Essays* for 1856, p. 61.) The legend has been rationalised by Herodotus, i. 3. The name seems to belong to the class which includes such epithets of the dawn as Euryanassa, Eurydika, Euryphassa, Eury-medusa, &c.

Europe. This western division of the northern part of the great continent, is the smallest of the political divisions of the world once called continents, and is not geographically distinguished or naturally separated either from Asia or Africa. The Ural Mountains, which separate it nominally from Asia, are low and unimportant, barely commanding a watershed; the Mediterranean, that disconnects it from

EUROPE

Africa, properly belongs entirely to it, together with the great chain of the Atlas. The mountain axis through Asia is continued entirely through Europe. The rivers of Europe are subordinate and inconsiderable, compared with those of Asia and America. The lakes are also small in comparison with those of the other great districts, but they are interesting and picturesque. Including its adjacent islands, the whole area of Europe is but three and three-quarter millions of square miles, and is only a little larger than Australia.

But there is one peculiarity of Europe, so marked and so important in its influence on man, as fully to explain its great advantages over other countries in some respects, and its present condition as the centre of the most progressive forms of civilisation. With so small an area as that described, and attached as it is to Asia by a long land frontier, the coast line of Europe is so wonderfully indented and broken by inland seas, gulfs, bays, and inlets, that its length is nearly 20,000 miles. The total estimated length of coast of all the land on both sides of the great Atlantic canal, including the inland seas, being little more than 55,000 miles, the enormous preponderance of European coast compared with that of an equal area of other lands may be easily understood. The north and west coast of Africa, the whole eastern coast of the two Americas, and the shores of the great gulfs of Mexico and the Caribbean Sea have together a length of coast less than double that of the west and south shores of Europe.

Europe possesses mountain ranges, river systems, lakes, plateaux, and low plains. All are deeply interesting and instructive, though so much smaller than those of the larger tracts of land. We proceed to notice briefly the chief outlines, referring to separate articles for those which possess special interest.

Mountain Chains.—The great and commanding mountain axis of Europe is the chain of the Alps; culminating towards the west between Switzerland, France, and Italy by the Mont Blanc and Monte Rosa groups, attaining a nearly equal elevation in the Oberland Alps, continuing at great elevation eastwards through the Tyrol to the Gross Glockner, continuing at lower elevation towards the east to connect with the CARPATHIANS, branching to the south-east to form the APENNINES, and afterwards the Dalmatian Alps extending into Greece and connecting with the BALKAN. The western continuation of the Alps forms the great chain of the PYRENEES.

The other mountain chains of Europe are the Scandinavian chain, continued into Scotland, Cumberland, and Wales; the Sierra Nevada, in Spain; the Vosges, and the mountains of the Black Forest, the Harz, the Erzgebirge, the Ichtelgebirge, Riesengebirge, and some others. The mountains of Central France form a group rather than a chain.

The following are the heights of the culminating peaks of the principal chains:—

EUROPE

Name of Chain	Name of Mountain	Height ft.
Alps . . .	Mont Blanc .	15,760
Sierra Nevada	Muley Hassan or Mulhacen }	11,660
Pyrenees . .	Maladetta .	11,168
Balkan . . .	Tchar Dag .	10,000
Apennines . .	Monte Corno	9,523
Carpathians		
(Tatra group)	Lomnits . .	8,779
Pindus . . .	Guiona . .	8,239
Dovra-feld . .	Snae-hattan .	8,122
Riesengebirge	Schnee-koppe	5,000
Grampians . .	Ben Nevis .	4,368
Cambrian	Snowdon . .	3,571
Mackgillcuddy's Reeks . . .	Carn Mal .	3,410

River Systems.—Of the river systems of Europe, the Danube is by far the most important; but it has only a secondary drainage, emptying into the Black Sea, which communicates with the great ocean through the whole course of the Mediterranean. Of the rivers entering the Atlantic, the Rhine is the principal.

The water systems of Europe are eminently favourable to navigation; for although the rivers are smaller than those of Asia and America, they are in all respects more useful and available. Most of them are now navigated by steamboats for a great distance into the interior of the continent, and some are made to communicate by artificial canals, so as to permit a complete internal system of water traffic.

The mountain axis acts as a complete water parting in Europe. No stream crosses the axis at a high level; and the only large river that runs north and south, and occupies transverse valleys, is the Rhône, which separates the Alps from the Pyrenees. The Danube indeed separates the Carpathian branch from the main chain; but it is bent aside by the Dalmatian Alps and the mountains of Greece, and no other river crosses any part of the main chain. The water systems of Europe are thus either north or south of the mountain axis, and the largest number and the most important are to the north. Except the Rhine and the rivers of France, all empty themselves into the Baltic; the direct Atlantic drainage being therefore very small. The drainage south of the mountain axis is chiefly into the Mediterranean and its smaller seas; but several of the rivers of the Spanish peninsula enter the Atlantic.

Except the Danube and the Volga (which is only partly a European river), the drainage areas in Europe are small. [RIVER SYSTEMS.] Of the various rivers, several have deltas; these are very extensive in the case of the Rhine, the Rhône, and the Danube. [DELTA.]

Lakes.—There are in Europe several lakes large in proportion to the area of the land, but small compared with the principal lakes of the earth. Lake Ladoga is the largest, having an area of about 1,400 square miles. It communicates with the gulf of Finland. There are several smaller lakes at no great distance. The

EUTERPE

Swiss and Italian lakes, though not large, are remarkable beyond all others for the exquisite and magnificent scenery surrounding them. They are all of fresh water, and are some of them deep mountain lakes, others being shallow and occupying mere depressions in the plains.

Plateaux and Low Plains.—The great plateau of Europe is the high land of the Iberian peninsula between the Pyrenees and the Mediterranean. It is flanked by short mountain chains crossing the country in various directions. The area of this table land is not less than 100,000 square miles. High land extends also through the middle of France. No elevated table lands occur in the Alps, although the great valley of Switzerland is much elevated above the sea. There is table land in and near Greece.

The low plains of Europe are very extensive on the north side of the mountain axis, and are only interrupted by mountains of secondary importance. They are almost continuous from the shores of the German Ocean and the Baltic to the foot of the Ural Mountains, and others extend southwards and connect with the extensive low lands of Asia. The greater part is very level, and not very much above the sea. [STEPPIES; PLATEAUX.]

Eurydice. [ORPHEUS.]

Eustachian Tube. Named after the celebrated Italian anatomist Bartholomew Eustachius, who is said to have discovered it, though it is accurately described by Aristotle, who quotes an earlier Greek anatomist, Alcmeon, as having known it. This communication between the ear and the mouth begins in the anterior part of the tympanum, and runs in a bony canal forwards and inwards, terminating with the petrous portion of the temporal bone. It then proceeds, partly cartilaginous and partly membranous, gradually enlarging to its termination behind the soft palate. It is through this tube of communication with the ear that persons who have a perforated tympanum blow tobacco smoke: when the Eustachian tube is stopped, or obliterated, it produces deafness. [EAR.]

Eustachian Valve. A semilunar membranous valve, which separates the right auricle of the heart from the inferior vena cava, first described by Eustachius.

Eustathians. In Ecclesiastical History, a sect of heretics of the fourth century; so called from their founder Eustathius, a monk whose opinions were condemned at the council of

(Gr. *εὐσταθες*). In Architecture, that intercolumniation, or space between columns, which, as the name imports, was considered the most beautiful, being two diameters and a quarter of the column in width.

Euterpe (Gr. *εὐτερπη*, *delightful*). A genus of graceful habited Palms found in the tropical parts of South America. *E. edulis* is the *Assai* Palm of Pará. It grows in swampy places, reaches thirty or forty feet in height, and bears fruit from which the natives manufacture *Assai*.

a beverage of a thick creamy consistence and of plum colour, which, when sweetened with sugar and thickened with cassava starch, is very nutritious.

EUTERPE (Gr.). In Mythology, one of the nine Muses. (Horace, *Ode* 1. l. 54; Hesiod. *Theog.* 77.)

Euthanasia (Gr. from *eû*, and *thavos*, death). Literally, an easy death. By political writers it is employed in various senses to indicate such peculiar theories as have the best tendency to uphold the state or disentangle it from difficulties. Thus, for instance, it is maintained that the issue of inconvertible paper money is the true *euthanasia* of public debts in modern countries.

Euthyne. [DOKIMASIA.]

Eutyhians. In Ecclesiastical History, sect of the fifth century, marked by the vehemence of their opposition to the heresy of the Nestorians. The latter had asserted the distinctness of the two natures in Christ; the Eutyhians confounded them together, and supposed the human to be merged in the divine. Their originator, Eutyche, was the abbot of a monastery at Constantinople, and was excommunicated in the year 448 by a synod which was convened there for that purpose. This decision was controverted by another council at Ephesus in the following year; but the new opinions were finally condemned by the council of Chalcedon in 451, which established the doctrine that Christ was perfect God and perfect man, consubstantial with the Father as to His divinity, and with man as to His humanity, the two natures being united in Him without conversion, without confusion, and without division.

Euxanthic Acid. *Purreic acid.* The pigment known as *Purres* or *Indian yellow* is the magnesia salt of purreic acid. Purreic acid forms pale yellow crystals; by heat it gives a sublimate of *euxanthone* (*purrenone*), and by the action of sulphuric acid yields *hamathionic acid*.

Euxanthine (Gr. *eû*, and *ξανθός*, yellow). A substance obtained from India under the name of *Purres* or *Indian yellow*. It is supposed to be derived from the bile or urine of the camel, buffalo, or elephant: it forms small pale yellow crystals.

Euxenite (Gr. *εὐξενος*, friendly). A mineral containing columbium, yttria, and uranium, found at Arendal in Norway.

Evangelical (Gr. *εὐαγγελικός*, from *εὐ-γελος*, messenger). A title assumed by different branches of different Protestant churches, by way of marking their peculiar orthodoxy. In Prussia, the United Lutheran and Calvinistic churches have styled themselves the *Evangelical church*.

Evangelist (Gr. *εὐαγγελιστής*). One who brings good tidings. Hence the authors of the Four Gospels are called *evangelists*.

Evaporation (Lat. *evaporatio*). The conversion of substances into vapour is one of the most important and general effects of heat. During this process, a considerable quantity of

sensible heat passes into the *latent* or *insensible* state. When a vessel of water is placed upon the fire, its temperature gradually rises till it attains 212°; then, although it remains upon the fire, and of course receives heat as before, it does not become hotter, but is gradually converted into steam or vapour: so that the effect of heat is not to elevate temperature, but to change state or form; that is, in the case of water, to convert it into steam. Hence we assume that steam, though not hotter than water, contains a much larger quantity of heat, and this heat again makes its appearance when the steam is condensed or re-converted into water. At whatever temperature vapour is produced, it is similarly constituted; and that which escapes from water at ordinary temperatures, by the process usually called *spontaneous evaporation*, resembles the former in all respects: hence it is that evaporation is to surrounding bodies a cooling process; and that in the converse change, or the return of the vapour to the liquid state, heat is evolved and rendered sensible. The same general phenomena are observed with all other liquids, and those which evaporate rapidly at common temperatures often give rise to the production of a great degree of cold; such as spirit of wine, or ether. If the latter fluid be suffered to dribble over the bulb of a thermometer, it will cause it to sink below the freezing point of water; and by accelerating similar cases of evaporation, we obtain most intense degrees of artificial cold.

The circumstances that principally influence the process of spontaneous evaporation are, extent of surface, and the state of the air as to temperature, dryness, stillness, and density.

Evectant. A peculiar kind of contravariant, formed by operating on any invariant of any quantic

$$a_0 x^n + n a_1 x^{n-1} y + n b_1 x^{n-1} s \\ + \frac{n(n-1)}{1.2} a_2 x^{n-2} y^2 + \&c. \dots$$

with the symbol

$$\left(\xi^n \frac{d}{da} + \xi^{n-1} \eta \frac{d}{da_1} + \xi^n - \zeta \frac{d}{db_1} \right. \\ \left. + \xi^{n-2} \eta^2 \frac{d}{da_2} + \&c. \dots \right)^p,$$

where the facients ξ, η, ζ, \dots are contragredient to x, y, z, \dots . Strictly speaking, the result of this operation should be called the *pth evectant*. Thus the discriminant of the ternary quadric

$$ax^2 + by^2 + cz^2 + 2dys + 2esz + 2fxy$$

being

$$abc + 2def - a^2d^2 - b^2e^2 - c^2f^2,$$

its first evectant is

$$(bc - d^2) \xi^2 + (ac - e^2) \eta^2 + (ab - f^2) \zeta^2 \\ + 2(af - ad) \zeta + 2(df - bc) \xi \zeta \\ + 2(de - cf) \xi \eta,$$

which is known to be a contravariant. [DISCRIMINANT AND CONTRAVARIANT.]

EVECTION

Evection (Lat. *erectio, a carrying out*). In Astronomy, an inequality of the moon's motion, depending on the position of the transverse axis of the lunar orbit in respect of the line of the syzygies, or line joining the sun and earth. When the transverse axis lies in the same direction with that line, the quantity by which the solar force diminishes the gravitation of the moon is greatest when the moon is in the apogee, and least in the perigee. In this situation of the orbit, therefore, the difference between the moon's gravitation at her apogee and perigee is increased by the solar action, and the orbit consequently appears to have its eccentricity augmented. When the line of the apogee is in the quadratures, the contrary happens; the difference between the amount of gravitation at the apogee and perigee is diminished, and the eccentricity of the orbit appears also to be diminished. The evection is proportional to the sine of twice the angular distance between the sun and moon, diminished by the moon's mean anomaly; and its greatest value amounts to $1^{\circ} 20' 29''$. This inequality (sometimes called the *second inequality* of the moon's motion, the equation of the centre being the *first*) was noticed by Hipparchus, and Ptolemy gave a construction which represents its general effects with great accuracy. The term *evection* was first applied to it by Bullialdus.

Even keel. A ship is said to be on an even keel when she draws the same water abaft as forward; the expression, however, often implies, though inaccurately, *not inclined to either side, or upright*.

Evergreen. In Garden Botany, a name applied to those plants whose leaves remain perfect upon a stem beyond a single season, as the Holly, the Fir tribe, and the Ivy. [DECIDUOUS.]

Everlasting Flowers. Certain flowers, chiefly of the *Composite*, whose hard tissue and deficient moisture enables them to retain their colour for several months after having been gathered. [AMARANTHUS.]

Evidence (Lat. *eventitia*). In Law, 'any matter of fact, the effect, tendency, or design of which, when presented to the mind, is to produce a persuasion, affirmation, or disaffirmation, of the existence of some other matter of fact.'

A witness, in a court of common law, is compelled to give his attendance, in civil cases, by subpoena, or by habeas corpus if the witness be in custody. The reasonable expenses both of going and returning must be tendered to the witness when he is served with the subpoena. A witness, refusing to attend on subpoena, may be attached for contempt of court, and is liable to an action at the suit of the party damaged. In criminal cases, the attendance of a witness for the prosecution is enforced either by subpoena, or more usually by the magistrates who take the depositions in the first instance binding him over to appear. His expenses, in a case of felony, are insured to him by statute. The de-

EVIDENCE

fendant may compel attendance of his witnesses by subpoena.

When the witness appears in court, objections may be taken to his competency. These objections are now reducible to two: want of understanding; want of religious belief. The first objection excludes persons of *non-sane memory* and also children too young or of too neglected education to understand the obligation of an oath: as to which they are questioned by the judge on the objection being taken. The second can now be sustained only in case of atheism or disbelief in a future state of reward and punishment: incompetency from interest, a principle derived from the civil law and formerly the source of much litigation, is now almost banished from our law; the only exceptions of importance being that by the Act 14 & 15 Vict. c. 99 a person charged with the commission of an indictable offence is not a competent witness, against himself. Several classes of witnesses, however, though competent, are not compellable: e.g. husbands and wives in criminal cases against each other: counsel and attorneys against their clients.

All testimony must be given under a judicial oath, with an exception only in favour of conscientious objections. [AFFIRMATION.]

Evidence, Immediate and Mediate.—Besides the exclusion of witnesses on the score of competency, large classes of evidence are inadmissible. Admissible evidence must be, in general, immediate; that is, it must convey the actual knowledge or belief of the witness. This rule excludes, as a general proposition, all hearsay; that is, all narration of the declarations made by others to the witness. There are, however, several classes of mediate testimony which are admissible. Such are, general reputation in certain cases; and declarations, made by a party to the suit, which contain admissions contrary to his own interest. So, in various cases, letters or entries made in books are admissible, where they contain similar admissions. Upon the same principle, the confession of a prisoner is evidence (if not extorted by fear or hope) in a criminal case. Depositions of a witness now deceased, but who had formerly given evidence on the same dispute, are admissible. Evidence may also be considered as divided into original or best, and secondary evidence. For instance, the reading of a document is better evidence of its contents than statements, either written or oral, respecting them. It is a general rule, that all secondary evidence is excluded, if better evidence (that is, evidence of a class which the law recognises as better) happen to be attainable.

Examination of Witnesses.—A witness, on being admitted in court, is first subjected to the examination of the party in whose behalf he is called, which is termed the *examination in chief*; and the principal rule to be observed by the party examining is, that leading questions are not to be asked. What are leading questions, it is not always easy to ascertain; but questions to which the answer Yes or No would be conclusive of the issue, fall undoubtedly within

EVIDENCE

this designation. All questions which suggest an answer may be considered, in one sense, as leading questions; but they are not all equally objectionable. The witness is then cross-examined by the opposite party. The object of cross-examination is twofold: to weaken the evidence given by the witness as to the fact in question, either by eliciting contradictions or new explanatory facts; or, secondly, to invalidate the general credit of the witness. In the latter case, it is a general rule, that a witness may refuse to answer any question, if his answer will expose him to criminal liability; and this, whether immediately or by collateral inference. Whether he can refuse to answer a question tending to disgrace him without involving him in danger, is a point which has been frequently debated, but which the general practice of our courts seems to settle in the affirmative. The credit of a witness may likewise be impeached by the general evidence of others as to his character. But in this case no evidence can be given of particular facts which militate against his general credit; as this would be in contravention of another rule, that collateral issues—questions of fact unconnected with the subject of dispute—shall not be raised during the course of a trial. Re-examination of a witness by the party who first examined him, must be directed to such new points only as have been raised by the cross-examination. If it is wished to put a question not connected with these points, the proper course is for the counsel to apply to the court to put the question for him.

Evidence, Documentary.—Written instruments, considered as evidence in a court of justice, have been divided into *public judicial documents*; *public non-judicial*; *private documents*; and *mixed*, which are partly public and partly private. The contents of the record of a court of justice are properly proved by inspection of the record itself; otherwise by *exemplification*, or by *sworn copy*. A copy of a record, under the seal of the Court of Chancery, or of one of the king's other courts, is an exemplification; as are also the records of some inferior tribunals. Office copies are evidence, wherever the law has intrusted a particular officer with the making of them. Sworn copies are copies proved on oath to have been examined with the original. All public documents, whether judicial or non-judicial, which cannot be removed, can be and usually are proved in this manner. But before it can be read, it must be proved that the original came out of the hands of the officer of the court, or from the proper place of deposit. A copy of a copy is in no case admissible.

Mixed documents are of a nature partly public and partly private; such as court-rolls of manors, and corporation books. Examined copies of these are evidence. The books of public companies—as, for instance, the East India Company—are evidence in questions between parties interested in them. Private writings are of two sorts: first, writings to

which the person against whom they are offered was party or privy; secondly, writings of third persons. All documents of the first class are, in general, evidence against the party. And an admission under seal (as a deed or bond) is, in general, conclusive evidence against the obligor, or party binding himself; that is, he is *estopped*, or prevented, from offering to rebut it.

A discussion of the rules which govern the admissibility of written instruments not under seal as evidence would occupy far too wide a field for the present purpose. Oral evidence can in no case be received as an equivalent or substitute for an instrument, where a writing is required by law; or to give effect to such an instrument, if defective in any particular required by law; or to vary its terms, if it have been appointed, either by act of law or by compact of the parties, as a memorial of the transaction between them. This rule proceeds on the general principle already adverted to, that where the best evidence can be had, secondary testimony shall not be substituted for it. But oral evidence is admissible in various cases, to explain, to restrict, and to defeat instruments, on the ground of fraud or mistake.

Entries in writing, as well as declarations by third persons, are in general excluded. The cases in which they may be admitted are, either where they serve to explain and accompany material facts; or, in some cases, on a principle of necessity, where the party who made them is supposed to have had peculiar grounds of knowledge as to the fact in dispute. In the first category, as a common instance, we may cite declarations of a trader at the time of his quitting his place of business, which are commonly received in evidence on bankruptcy questions. The second may be instanced by entries of bailiffs or stewards, which are received where the payment of rent is disputed.

Proof of Written Documents.—This is effected either by witnesses, by admission of the adversary, or by enrollment; the latter mode of proof being confined to a few classes of documents by virtue of Acts of Parliament.

In the first and common mode of proof, the instrument must either be produced, or its absence must be accounted for by loss or destruction (and if either of these negative assertions, as they may be called, cannot be directly proved, evidence of diligent search will be received, and its contents may be proved by counterpart or secondary evidence); or it must be proved to be in possession of the adversary, and that notice was given him to produce it. In the case where the instrument itself is produced, it is either attested or not attested. If the former, the attesting witness must be called; or his absence must be accounted for, and his handwriting proved; or it must appear that the instrument is thirty years old, and has come out of proper custody, in which case its authenticity is presumed. Where a subscribing witness is called to prove a deed, proof of sealing and delivery is required from him: where there are several subscribing witnesses, one is sufficient. Where

EVOCATI

there are no attesting witnesses to an instrument, the handwriting of the party binding himself is generally sufficient proof. On the proof of handwriting—a very difficult matter of evidence—we can only observe, that it is ordinarily proved by the testimony of a witness who has acquired a general knowledge of the party's hand, either by having seen him write (although but once), or by a correspondence with him, or other transactions. Evidence by comparison of handwriting was formerly not receivable, and this although a skilled person offered his opinion, but this rule is now abolished by statute. *Public documents*, when the originals are not procurable, are commonly proved by examined copies, but their proof has been greatly facilitated by a series of modern statutes. For the law of evidence in Scotland, see especially the treatise of Dickson, 1856.

Evidence of Parties.—An important enactment was passed in the 14 & 15 Vict. c. 99, by virtue of which parties to suits, actions, or other proceedings in any court of justice are admitted witnesses. It provides that on the trial of any issue joined, or of any matter or question, or on any enquiry arising in any suit, action, or other proceeding in any court of justice, or before any person having by law, or the consent of parties, authority to hear, receive, and examine evidence, the parties thereto, and the persons in whose behalf any such suit, action, or other proceeding may be brought or defended, shall be competent and compellable to give evidence either *vivâ voce* or by deposition, according to the practice of the court, on behalf of either or any of the parties to the suit, action, or other proceeding. By this clause, in addition to the parties offering themselves to give evidence in their own behalf, their opponents can compel them to give evidence in the cause. Nothing in the Act is to compel persons charged with criminal offences to give evidence, nor is the Act to apply to proceedings in consequence of adultery. Further, the new law authorises the common law courts to compel an inspection of documents whenever equity would grant a discovery. Foreign and colonial acts, judgments, &c., are to be received in evidence, without proof of the seal or signature; so, also, are apothecaries' certificates. Documents are to be admitted in England or Ireland from either place, and the colonies, without proof of seal. Persons forging the seal or signature to be guilty of felony, and punished accordingly. This Act, which extends to all parts of the United Kingdom except Scotland, came into force on November 1, 1851.

Evocati (Lat. *called out*). In the ancient Roman army, soldiers were so named who, having received their missio, or discharge, were again called out for military service.

Evolute (Lat. *evolutus*, part. of *evolvere*, *I roll out*). If a perfectly flexible and inextensible string be conceived to be wrapped around any plane curve, then on unwrapping the same under tension, each point of the string will describe a curve of which the first curve is

EVOLUTE

said to be the evolute. The curves described by the several points of the string, therefore, have the same evolute; they constitute a series of *parallel curves*, which are said to be *involute*s of the curve by whose evolution they are generated. The theory of evolutes was first examined by Huygens in his *Horologium Oscillatorium*, his object being to find the evolute of the common cycloid with a view of causing pendulums to vibrate in cycloidal arcs, and thus of securing the property of isochronism. [CYCLOID.] The evolute of a curve may obviously be regarded either as the envelope of the normals to a curve or as the locus of its centres of curvature. In most text-books the subject will be found treated from both points of view, and the methods of obtaining the equation of the evolute fully described. From the definition of a plane evolute it follows that it is a rectifiable curve, for the difference between the radii of curvature at any two points of a curve is obviously equal to the arc of the evolute joining the centres of curvature. In general, the evolute of a plane curve of the n^{th} order is of the order $3n(n-1)$ and class n^2 ; both these numbers, however, are subject to reduction in presence of certain singularities. (Salmon's *Higher Plane Curves*.) The class of the evolute gives, of course, the number of normals which can be let fall upon the curve from any point p in the plane. That this number is equal to n^2 has been very simply shown, by Steiner, in a most instructive paper on 'Algebraische Curven und Flächen' in Crelle's *Journal* (vol. xlix. 1855).

Besides the plane evolute hitherto considered, however, a plane curve has an infinite number of non-plane evolutes; in other words, there are innumerable curves in space, which on being unwrapped in the manner described will generate the given curve. This is best seen by considering the evolutes of non-plane curves in general. Let m be any one of the normals at a point m of such a curve, and let e be the point (on the polar line) in which it is intersected by the normal plane at the consecutive point m_1 ; then em_1 will be the only consecutive normal which will intersect em . Similarly em_1 will be intersected, say in e_1 , by a consecutive normal e_1m_2 , and so on; in short, the whole series of intersecting normals which em determines will form a developable surface, the cuspidal edge e, e_1, e_2 , &c. of which will obviously be an evolute of the curve m, m_1, m_2 , &c. This evolute (e), however, is only one of an infinite number corresponding to all possible directions of the initial normal em . The whole series, however, consists of geodesic curves, situated on the polar developable. They are geodesics because every osculating plane em_1m_2 of the evolute (e), since it passes through the tangent m_1m_2 of the curve, passes also through its parallel, the normal at e of the polar developable.

From this it is evident that besides its plane evolute, every plane curve has an infinite series of *helical evolutes*, situated on the cylinder

perpendicular to the plane of the curve, and having the plane evolute for its base.

The evolutes of a spherical curve are all situated on the concentric cone which forms the polar surface. This cone cuts the sphere in the *spherical evolute* of the curve, which is the envelope of great circles normal to the curve, and must not be mistaken for one of the series of evolutes before considered. It is manifestly not a geodesic on the polar surface.

Spherical evolutes are merely particular cases of others, situated on any surface whatever, upon which the primitive curve is supposed to be traced. These may be defined as the envelopes of geodesic normals to the curve.

The tangent of the original curve is of course parallel to the normal of its evolute, which latter envelops a *second evolute*, whose elements are parallel to those of the curve and perpendicular to the corresponding elements of the first evolute. Proceeding in the same manner, a series of evolutes are obtained the angles of contact of which are all equal at corresponding points. Euler has shown that the logarithmic spiral is the only curve whose evolutes are all similar to itself. Hypocycloids and epicycloids, which include the common cycloid as a particular case, are the only curves whose first evolutes are similar to themselves, and in an inverted position.

Evolution (Lat. *evolutio*, an unfolding). In Algebra and Arithmetic, the extraction of roots; in other words, the inverse operation to involution. The object of evolution, therefore, is to ascertain the quantity which multiplied by itself a stated number of times yields a given result. In a wider sense, evolution may be regarded as synonymous with the solution of a binomial equation, for it is obvious that the n^{th} root of any number a satisfies, or is a root of, the equation $x^n - a = 0$. This root is indicated by the symbol $\sqrt[n]{a}$ or $a^{\frac{1}{n}}$. The

methods of extracting square and cube roots are given in all elementary works; and Horner's method of extracting any root whatever, or rather of solving, approximately, any numerical equation, now finds a place in every good algebraical text-book.

Evolution. In Physiology, that theory of generation in which the germ is held to pre-exist in the parent, and its parts to be unfolded and expanded, but not actually formed, by the procreative acts. The principal and most consistent supporters of this theory maintain that the first created individuals contained the germs of all future possible successors, successively included one within the other; and that generation is merely the act of unfolding, or an evolution of the germ: Swammerdam, Bonnet, Spallanzani, Haller, and Cuvier maintain this theory.

The theory of evolution is opposed to that of epigenesis generation, in which the germ is held to be actually formed as well as expanded by virtue of the procreative powers of the parent. Its chief supporters are Harvey, Caspar

Fred. Wolff, Blumenbach, and the professors of the modern German physiological school.

Evolutions, Military. The movements by which troops change the order, position, and direction of their primary formation. All evolutions are performed according to a regulated system, which differs in its details in the armies of various nations; though in all of them simplicity, facility, and rapidity of movement are the points aimed at. It is probable that the precision and quickness of fire of the rifled arms now introduced will entail a great change in the existing systems of evolutions.

Evonymine. A crystalline, neutral, bitter principle found in *Euonymus europæus*.

Evows. In Music, the vowels used with the ending notes of the ecclesiastical tones: the word is formed of the six vowels in the words *saculorum amen*, which are subjoined to the notes in Antiphonaries, &c., to indicate that those are the ending notes.

Ex Cathedrâ. A Latin phrase; originally applied to decisions given by prelates, chiefly popes, from their cathedra or chair: i. e. in a solemn judicial manner. Hence applied to every decision pronounced by one in the exercise of his peculiar authority: a professor in his lecture room, a judge from the bench, &c.

Ex Officio (Lat. *by reason of office or duty*). In general language, every act done by an officer either in prosecution of the general duty of his office, or in executing some special duty imposed by it, is said to be done *ex officio*. But, in more strict phraseology, a proceeding *ex officio* is one taken by an officer of his own will, in execution of what he takes to be the duty of his office; as, where a justice of the peace demands and takes surety of his own discretion, without the request of the injured party. An *ex officio* information is an information at the suit of the king, filed by the Attorney-General, without applying to a court for leave. [INFORMATION.] *Ex officio* criminal informations are employed in cases of libel, sedition, &c., when officially prosecuted.

Ex Parte (Lat.). In Law, *of the one part*. A commission *ex parte* in chancery is that which is taken out and executed by one side or party alone, on the other party's neglecting or refusing to join.

Ex Post Facto (Low Lat. literally, *by something done afterwards*). A punishment which is inflicted in consequence of a law made with a view to a particular offence already committed is said to be inflicted *ex post facto*; and the phrase *an ex post facto law* is popularly applied to all laws enacted with a retrospective effect and with an intention to produce that effect, which is justly regarded as tyrannical. That species of laws which the Romans termed *privilegia*, i. e. laws passed in order to impose restrictions on individual citizens, were frequently *ex post facto*. The English practice of a *bill of pains and penalties* is a species of *ex post facto* legislation, and was much animadverted on in the debates which took place on the occasion of its adoption against Queen Caroline in 1820.

EXACERBATION

Exacerbation (Lat. *exacerbatio*). An increase in the violence of symptoms of disease; as of pain, or especially of fever.

Excresis (Gr. *ἐκρείσις*, a taking out). One of the divisions of Surgery adopted by old writers, and confined to operations concerned in the removal of parts of the body.

Exaltados. In Spanish History, the name of the party attached to what has been vulgarly termed the *liberal* system of politics, corresponding to the *extrême gauche* of the French, or Whig-radicals among ourselves.

Exaltation of the Cross. A feast of the Romish church, celebrated on September 14, to commemorate the restoration to Calvary, in 628, of the Cross which had been carried off fourteen years before by the Persian king Chosroes.

Examiners. In Law, officers of the Court of Chancery appointed to examine witnesses on either side. The evidence taken by them follows the rules for evidence given in the common law courts.

Exangia (Gr. *ἔξις*, and *ἀγγεῖον*, a vessel). A term applied by some medical writers to diseases in which large blood-vessels are broken or perforated, or enlarged, without any external opening: it includes *aneurism*, *varix*, and *cyanea*.

Exanthalose (Gr. *ἐκάνθησις*, efflorescence). A name given by Beudant to native *sulphate of soda*, occurring as an *efflorescence* on certain lavas, and elsewhere.

Exanthematous (Gr. *ἐκάνθησις*, to effloresce or break out on the surface). A term which includes in its meaning all eruptive diseases accompanied by fever.

Exarch (Gr. *ἐπαρχος*). The title of the viceroys of the Byzantine emperors in the provinces of Italy and Africa after they had been reconquered by Justinian. The exarch of the former province fixed the seat of his government at Ravenna. They were also styled *patricians*. The exarch of a diocese was, at first, the same as the primate. The term was also applied in the Eastern church to the general or superior over several monasteries; and it further denotes the deputy of the patriarch, whose duty it is to visit the churches and clergy in the provinces allotted to him.

Exautorati (Lat.). In Roman military practice, soldiers were so called who, having served for sixteen years, remained under a *vexillum* or standard of their own for four years longer, when they received a full discharge. After the fall of the republic, the word *ex-auctorare* came to be used chiefly in the sense of cashiering for misconduct. [EVOCATI.]

Exauguration (Lat. *exauguratio*). In Roman Antiquities, the act of changing a sacred thing into a profane one. It was performed, as the name implies, by the augurs, who first consulted the gods to know whether they gave their consent. This process was necessary in the case of consecrated persons as well as of sacred buildings; priests could not without this ceremony give up their functions, or (if bound to celibacy) enter into matrimony.

EXCESS, SPHERICAL

Exocaria (Lat. *exoco*, to make blind). The *E. Agallochum*, an Eastern species of this genus of *Euphorbiaceæ*, has been supposed to be the source of Aloes or Eagle wood, which is now, however, known to be produced by *Aquilaria Agallochum*. It is a small tree with acrid milky juice, which if it gets into the eyes causes blindness. The wood is sometimes used as firewood, but the smoke from it is said to occasion intolerable pain in the eyes. The greater part of the species are West Indian or South American.

Excambion (Ital. *cambio*, exchange). In Scotch law, the name given to the contract by which one piece of land is exchanged for another.

Excellency. A title of honour in various European states. It was borne, successively, by the Lombard kings; by some emperors of the West; by various minor Italian potentates; and it is now appropriated to persons in the actual execution of certain official services; ministers, some court dignitaries, and ambassadors, but not *chargés d'affaires*. Governors of English colonies are styled *excellency*.

Excentric (Lat. *ex*, out, and *centrum*, centre). In the ancient Astronomy, the deferent circle in the circumference of which the centre of the epicycle of a planet is carried forward in its orbit round the earth. It was *excentric* in respect of the earth; that is, though the orbit of a planet was a circle described about the earth, the earth was not placed at the centre of that circle. In modern Astronomy, the *excentric* is the circle which circumscribes the elliptic orbit of a planet. [ANOMALY.]

Excentric. In Machinery, a wheel in which the axis is removed from the centre of the figure, or of which the periphery is not circular. Excentrics are used for converting circular motion into alternating, rectilinear, or intermittent motion, and are usually driven by bands or straps.

Excentric Angle. In Geometry, the same as the *excentric anomaly* in Astronomy. [ANOMALY.] The introduction of this angle is frequently of service in the treatment of geometrical questions concerning the ellipse. [ELLIPSE.]

Excentricity. In Astronomy, the distance of the foci from the centre of the elliptic orbit of a planet or satellite, the semi axis major being regarded as unity; it may also be defined as the ratio of the distance between the focus and centre to the semi axis major. Thus, if *a* and *b* denote respectively the semi axes major and minor, and *e* the excentricity, we have $ae = \sqrt{a^2 - b^2}$. *Excentricity* is thus to be carefully distinguished from *ellipticity*, which denotes the ratio of the difference of the two axes to the greater. [PLANET.]

Exception (Lat. *exceptio*). In Law, a stop or stay to an action. In common law proceedings, a denial of a matter alleged in bar to an action. In chancery, what is alleged against the sufficiency of an answer.

Excess, Spherical. [SPHERICAL EXCESS.]

EXCHANGE

Exchange (Fr. *échange*). In Political Economy, the mutual interpretation of utilities when measured by some common standard of price. The equation of value in commodities. The satisfaction of supply and demand in such objects as possess an economical value.

Many objects may possess a great value to mankind, and yet not be susceptible of any economical estimate. Some of these are natural, as the qualities or forces of objects. There is infinite value in the physical properties of iron, in the power of wind as a motive force, and in the qualities of water as supplying the means for a road on which comparatively small friction is experienced. But these powers being universal, have no economical value. Although great importance is to be assigned to those characteristics of gold and silver which make them so apt to supply the needs of a currency, these peculiarities, though of high economical significance, have no economical value. The same reasoning applies to the moral qualities of individuals and communities. These qualities may be, and commonly are, the foundation of material progress and comparative wealth; but as they are not commensurable with any other object, they cannot be estimated by any standard of price, and they consequently have no value in *exchange*, however important may be their value in *use*. On the other hand, many products of labour may have no value in use, may even tend to deteriorate the character and capacity of those who produce and purchase them, but have an economical value because they can be measured by prices, and be exchanged against other commodities. It may be very desirable that their production should be diminished, or should wholly cease, and the labour devoted to their acquisition be turned to some other object or objects; but they are all objects of economical value, because they may be the material of exchange, and thus have a value in exchange.

A sale is an incomplete exchange, or, as J. B. Say has expressed it, is half an exchange. When a seller receives money in satisfaction of something which he has resigned to the use of another, he does not take the money because he can devote it, by any natural qualities which it possesses, to any personal service of his own (unless he melts it in order to manufacture plate from it, or to use it otherwise in the arts); but because it possesses certain conventional qualities, those namely which belong to it as a universal factor, in procuring whatever he may need hereafter, at little or no depreciation in its intrinsic or cost value. Gold and silver are produced in nearly equal quantities by nearly equal labour; and therefore their values, as measured by themselves, have the general characteristic of invariability in price. This fundamental fact in the nature of money is recognised by Aristotle, who says that 'money is a pledge of the power of future exchange,' and that 'while it varies in its own value, it does so less than any other commodity.' (*Éthic. Nic. 5. 5. 11 & 14.*)

The exchange is completed when the money

received for some commodity is again resigned, in compensation for a service or utility rendered either by the first purchaser, or far more commonly by some other person. In the division of occupations, the article in which one person deals may require a large market; that in which another trades, a small market; and thus it would not be possible for trade to be limited to the mutual exchanges of two persons. A town, for instance, the demands of which would suffice to maintain only one brewer, may be able to support ten grocers. By the circulation, however, of money, exchanges may be indirectly effected between all the persons resident in the town, and similarly between persons residing in different towns, and ultimately between persons residing and carrying on commerce in different countries. As a man's expenditure is necessarily regulated by his income, so a nation's trade is enlarged and diminished by the amount of its exports; and just as it is not necessary that a person B should exchange with one other person only, but may buy of A far more than he sells to him, so the excess of importation from one country must be ultimately balanced by an excess of exportation to another; just as the whole purchases of B must be regulated by his whole receipts.

So closely is the doctrine of exchange connected with economical values, that some economists, De Quincey for instance, have urged that exchange forms the actual centre of the system, and that the truer and more significant term for the science should be *catalactics*, or the science of exchanges. No doubt, from a purely analytical point of view, such a theory could be urged with great force, and it must be admitted that the method would give that precision to economical inferences in which they are as yet very deficient.

But on the other hand, what may be called the synthetical theory of the science commends itself more—proper precautions being taken for exactness—both on the ground of its didactic value, and from its breadth and fulness. Wealth is a state as well as a quantity; and in the former estimate, it will be impossible to exclude the consideration of those indirect forces which really contribute to the state of wealth, though it would not be possible, or at least easy, to interpret their position in discussing the process of production, or in resolving the bare act of exchange into its elements. To consider the act of exchange only in relation to wealth, would be, to use a close analogy, similar to the development of a theory of logic which should take account of the syllogism only, and should not only omit all mention of the inductive process, but should decline to consider the qualities of concepts; the relation of language to thought, and the properties of propositions; to confine economical anatomy to the skeleton, and ignore the rest of the organisation.

Society, from the point of view taken by economists, is an organisation in which mutual needs are met by mutual benefits; a gain in

EXCHANGE

the act of exchange occurring to both parties who enter into mutual contracts. This fact that there is a gain to both persons is fundamental in all trade; and applies equally to home and foreign trade; though so great a man as Bacon was led to believe that the profit of English trade was a loss to the trade of foreigners, and though so many attempts have been made to further supposed interests by legislative and fiscal expedients. Hence, as there can be no means by which this mutual gain can be interpreted except from the wishes of the contracting parties, and as any interference with the will at once weakens its force, and diminishes its capacity for determining what constitutes its best interests, freedom is as essential in exchange as it is in morals. In Economics, the interference with the judgment of the parties to an exchange is in ordinary cases sure to make economical action cramped, distorted, or paralysed.

Where slavery prevails, all the benefit is on one side; for no person, unless inveterately stupid, would continue to be a loser in the contract, except by force. In such a social state, one of the parties in production, occupying a position from which there is no escape, has no motive for improving his capacity, since all improvements in production, and all substitutions for labour, are primarily due to the disposition on the part of labour to shorten its own exertions by the intelligence which appropriates and directs other supplementary forces. No one will work well who has no possible means for serving himself, nor will anyone work intelligently who is absolutely debarred from reaping any of the fruits of his own intelligence. Hence, where slavery prevails, that state which economists call *stationary* is soon reached; in other words, the accumulation of wealth ceases; whereas when exchange is free, those motives are always present by which greater results are obtained from equal areas and equal capitals at less cost, and the state of economical progress is assured.

The moral and material instincts of mankind have combined to abolish slavery from the greater part of the civilised world. But other arrangements, only less hostile to the accumulation of wealth, and its equitable, that is its natural, distribution, still prevail in many countries, in the regulated trades and protective traffic of different communities. Protective systems have been adopted on very different grounds. Sometimes they are defended from their supposed benefit in furthering such industrial occupations as seem to have considerable political or social advantages implied in their adoption or prosecution. Sometimes they have been accorded as a counterpoise to supposed peculiar burdens levied on certain classes of the community. Occasionally they have been allowed in consideration of certain real services supplied by particular corporations. Some of these protective acts exist in our own country; many of them are clung to in other communities, and always mischievously. [PROTECTION.]

Though, however, on general grounds, the

freedom of individuals in acts of exchange must be vindicated, yet there are certain circumstances affecting certain persons, permanently or temporarily, in which a subsidiary control must be exercised. No one doubts, for instance, that there is a period of incapacity during which persons, by reason of their age or condition, are unable to cope with those who are more capable of gaining the advantage of a commercial transaction. The maxim *Caveat emptor* does not apply to a child or a lunatic, any more than the ordinary rules of moral obligations do, and the ordinary responsibilities of moral actions. But the exercise of authority in cases where the individual is only temporarily incapable of appreciating the terms of a contract is always relative to the temporary incapacity only. Authority is never a substitute for action, but can only be an aid to it.

Omitting, then, those cases in which non-age or mental weakness require that the general right of action should be delegated, those invasions only of *laissez faire* can be defended in which a monopoly price can be exacted from one of the parties, or in which the sagacity of an administration recognises that certain prospective advantages may occur to society by a course of action the value of which is not understood at present, but will certainly be understood hereafter.

The most notable among these instances are: First, the right of government to regulate certain charges for necessities, as for example the transit of passengers and goods by railways; the power of charge being in these cases completely at the discretion of the managers of the railway, and wholly removed from a true competition; for it is clear that at present no method of carriage can equal a railway in quickness and precision, and nothing can prevent, even in case two railways supply transit from the same place, a combination between the directors of both to raise rates, in accordance with the vulgar instinct that high prices mean high profits. In such a case, it is not only a privilege, but a duty of government to regulate the charge at which the service is rendered. Secondly, it is equally regular for government to interfere in order to secure the advantages of education, in the best sense of the word, to all classes of the community. Uninstructed people are so little informed about the benefits which ensue to themselves by the fact that they are properly educated, and even parents are so little careful of what is their real duty to their children, that if one waited till the time at which they might become alive to its necessity, the best opportunities would be lost. It has been proved repeatedly that the comparative progress of nations depends largely on the extent to which the means of a sound national education are supplied; and it is known in practice that the spread of a good system of education is the best means for eliminating social vices and miseries, for inculcating morality, and for securing the largest national benefits. The same reasoning, on the other

EXCHANGE, BILL OF

hand, applies to such endowments or supports learning and religious teaching as are needed in order to secure the recipients the leisure or capacity for the social advantages which they supply. As long as men are not alive to the

which is derived from the highest education, it is mere folly to repudiate the assistance of such means as sustain the most valuable of social services, before the value itself is recognised and estimated. When the recognition is complete, the aid may be abandoned.

Exchange, Bill of. An instrument which contains an order of payment on a debtor at a distance from his creditor, and which may thus become a means for liquidating transactions by transference to some third party, without the actual conveyance of specie.

It is clear, if trade be carried on between two towns, or two countries, and debts are contracted by reason of this trade, that great loss will ensue, from the necessity of perpetually transmitting money to and from each of these localities, and that expedients will be adopted to shorten the labour and expense of the transaction. In other words, accounts or debts may be written off against each other by the interchange of written instruments declaring the quantity of debt, and issued in confidence that the obligations created and acknowledged will be met when the document is presented for payment. This commercial confidence is quite distinct from public credit, is protected by its vital importance to the mercantile world, and must be guarded by strict regulations and even penalties upon breach of faith.

So important is the economy of this machinery, that expedients virtually equivalent to the creation of bills of exchange have been adopted in all such civilised communities as encourage or require any considerable trade. Tallies presentable at the various banks in the chief cities were familiar to the Greeks in the classical age, and orders on bankers in distant places were frequently given to merchants and travellers in order to avoid the cost and risks of carrying specie. The speech of Demosthenes against Callippus gives full information as to the manner in which bankers' books and securities were kept in Athens, as well as of their system of exchanges.

Similarly, the Romans invented mercantile instruments, under the name of *literæ cambiales*, which answered all the purposes of bills of exchange. Even were we not possessed of evidence as to the existence of the practice, we might be sure that the expedient would be adopted in the perpetual need for the transfer of tribute to Rome, and the payment of troops in the provinces.

It is said that either the Caursini or the Lombard merchants in the thirteenth century were the first to introduce the system into the mercantile arrangements of modern Europe; and it has been held that the notorious transmission of the profits of English benefices to foreign ecclesiastics, appointed by papal provisions, first called these instruments into

existence in England. In all likelihood, however, the custom had prevailed long before; and the attention awakened by the magnitude of the transactions at the period referred to, has been mistaken for the commencement of the practice. This country had from very remote times a considerable export and import trade with the Continent, the exports consisting of farm produce, especially wool; and the imports comprising the linens of Flanders, the silks of Italy, and the spices carried by the Italian merchants from the East by the two overland routes to Trebizond and Antioch, and the sea route through Aden, Cous, and Cairo. This trade in exports and imports would have naturally called bills of exchange into existence.

Among cities or countries having any considerable intercourse together, the debts mutually due by each other tend to an equality. There are at all times, for example, a considerable number of persons in London indebted to Hamburg; but, speaking generally, there are about an equal number of persons in London to whom Hamburg is indebted; and hence, when A of London has a payment to make to B of Hamburg, he does not remit an equivalent sum of money to the latter, but he goes into the market and buys a bill upon Hamburg for an equal amount—that is, he buys an order from C of London, addressed to his debtor D of Hamburg, directing him to pay the amount to A or his order. A having endorsed this bill or order, sends it to B, who receives payment from his neighbour D. The convenience of all parties is consulted by a transaction of this sort. The debts due by A to B, and by D to C, are extinguished without the intervention of any money. A of London pays C of ditto, and D of Hamburg pays B of ditto. The debtor in one place is substituted for the debtor in another; and a postage or two, with the stamp for the bill, form the whole expenses.

In mercantile phraseology, the person who draws a bill is termed the *drawer*; the person in whose favour it is drawn, the *remitter*; the person on whom it is drawn, the *drawee*, and after he has accepted, the *acceptor*. Those persons into whose hands the bill may have passed previously to its being paid are, from their writing their names on the back, termed *endorsees*; and the person in whose possession the bill is at any given period is termed the *holder* or possessor.

The negotiation of inland bills of exchange, or of those drawn in one part of the United Kingdom on another, is almost wholly in the hands of bankers. Many of the banks established in different parts of the country have direct intercourse with each other, and all of them have correspondents in London. Hence an individual residing in any part of the country who may wish to make a payment in any other part, however distant, may effect his object by applying to the nearest bank. Thus, suppose A of Penzance has a payment to make to B of Inverness. To send the money by post would be hazardous; and if there were fractional parts

EXCHANGE, BILL OF

of a pound in the sum, it would hardly be practicable to make use of the post. How, then, will A manage? He will pay the sum to a banker in Penzance, and his creditor in Inverness will receive it from a banker there. The transaction is very simple. The Penzance banker instructs his correspondent in London to pay to the London correspondent of a banker in Inverness the sum in question, on account of B; and the Inverness banker being advised in course of post of what has been done, hands over the money to B. The whole charges are limited to a trifling commission and twopence for postage, so that the affair is transacted in the cheapest as well as in the most commodious possible manner. Such a system is not only the most advantageous to the parties, but also to the public, who are thus enabled to dispense with as much as possible of the dear materials, gold and silver, and to make the fullest use of that which remains in their hands and forms the substratum of all these transactions.

Generally, bills of exchange are not payable at sight, but at a future date specified in the document; this date being ordinarily three months after acceptance. But there is nothing to prevent a bill being drawn so as to be payable at sight, that is on presentment, the postponement of the payment being relative to another commercial practice, that of procuring the funds, hereafter to be secured from the sale of commodities, by anticipation, and by paying a certain sum, called *discount*, in consideration of the advances made.

It has been stated that a bill of exchange may be transferred to a multiplicity of persons, each of whom on transferring endorses his name on the back of the instrument. When this endorsement is made payable to the *order of the transferee*, it is called *special*; when only the signature of the *transferor* is given, it is called *general*. Thus if the person holding a bill transfers it to the order of A B, the transference is of the former kind; if he simply writes his name across it, of the latter. A special order, as it creates a particular interest in the bill, which cannot without forgery be appropriated by another, is the safer method.

Bills are often drawn in sets, the first being accepted, and all being discharged on the payment of that accepted. The first of a set is generally sent without endorsement, in order that it may be accepted, and kept until demanded by the holder of one of the other bills. When the accepted first bill and endorsed second are wafered together, they become one bill in law.

Each endorser is liable for the payment of a bill in case the drawee or acceptor does not pay it; the names of endorsers forming accumulated security. Hence it may happen, that the credit of one endorser being higher or of more significance than that of others, a bill may increase in value, or, what is in effect the same thing, be negotiable at a lower rate of discount by the existence of the particular endorsement. It is said that this fact has been made the

means by which great profits have been secured by bill-brokers where commercial character is high.

The amount of foreign bills is generally expressed in the currency of the country in which the bill is to be paid; thus a bill drawn in London on a house in France would be expressed in francs and centimes. Sometimes, however, it is expressed in the currency of the country in which the drawer trades. Thus a bill drawn on France, but negotiated in London, is frequently expressed in sterling. In this case it is the practice to pay the amount at the rate of exchange which existed on the day at which the bill was endorsed or negotiated.

When the law of the place requires it, bills must be drawn upon stamps. The days of grace, that is the period after date at which the bill must be presented, are in England three. If, however, the third day be a Sunday, Christmas-day, or Good Friday, the bill is reckoned due the day before.

Bills of exchange, when based on what are called *real transactions*, are a means by which the capital possessed by lenders is rendered available for the activity and capacity of borrowers; that is, they tend to utilise and circulate capital which would otherwise be dormant. Such are the great mass of bills negotiated in the course of trade. A man sells goods, and accepts in place of present payment a bill from the purchaser, which bill is discounted in the usual form, the amount being met at the date specified, under certain commercial and legal penalties, by the acceptor, who provides for it by the resale of the goods purchased.

But of course it is possible, if precautions can be taken to prevent detection, for two persons assuming the appearance of drawer and acceptor to create and negotiate bills which are based upon no real transaction at all, and therefore to be deficient in the requisite stability of a sale and transfer of goods. Such bills are called *accommodation* or *feictitious bills*, and the circulation of such paper is an injury to legitimate trade, a material for rash and dishonest speculation, and a mischief to the public at large. It is an injury to trade, because such a competition for accommodation in the money market, especially when it is likely to be large in its amount, raises the rate of discount, and so diminishes the profits of the honest and *bonâ fide* trader; it leads to speculation of the worst kind, because the disposition to avow in a commercial instrument that value has been received, in other words that a real transaction lies at the bottom of the bill, when no such transaction has taken place, and no such value has been received, implies a fortiori that the creation of such documents has for its end some venture which would not be recognised on its own merits; and it is a public mischief, because, as all purchases affect prices, and as only those purchases affect prices legitimately which are founded on the demand of consumers and the amount of produce available for their use, such speculative transactions as are likely to give occasion

EXCHANGE, PAR OF

to these forms of paper credit raise prices beyond their true or market rate, and operate disadvantageously on the public. Many of the worst cases of commercial dishonesty and fraudulent bankruptcy are traceable to the practice of drawing and accepting accommodation bills.

Exchange, Par of. If the coins of any country, estimated at their mintage valuations, are compared with the coins of another country, estimated also under similar conditions, the proportion deduced from such a comparison is called a *par of exchange*. Thus, for instance, the French gold coin is only $\frac{2}{3}$ ths fine, while English gold is $\frac{23}{24}$ ths fine. Again, there is a retenue or charge for coining gold and silver in France amounting to six francs on the kilogramme in gold, and two francs on the kilogramme in silver. Hence, while the kilogramme of coined gold is valued at 3,100 francs, and that of silver at 200 francs, the prices paid by the Mint are 3,094 and 198 francs respectively. Under such circumstances the settlement of the par of exchange must take into account these variations and deductions.

On the other hand, the par of exchange, in the estimate of silver coins in this country, must take into account the fact that silver is purposely over-valued by the Mint regulations. Were French coins estimated in the British silver currency, without such calculations, the par in silver would be 1*l.* = 23 francs 24 centimes; while the par in gold would be (without any agio) 1*l.* = 25 francs 22 centimes.

Except, therefore, in estimating the value of coins actually imported from foreign countries, the par of exchange is of no practical significance; and as gold is not generally the standard of value in other countries, but bears an agio or premium varying with the circumstances of the case, the valuation of foreign coin becomes in effect a valuation of bullion.

Exchange, Rate of. By this term meant the price of the money of one country reckoned in the money of another country. In one country the rate is fixed, in the other variable. In exchanges between London and Paris, the rate is the value received for the pound sterling. In exchanges between London and Madrid, the value given is a variable amount in pence for the hard dollar. Hence in the rate between London and Paris, sterling is fixed; in the rate between London and Madrid, sterling is variable: the negotiator being said to give in the latter, and to receive in the former case.

The course of exchange from London, in receiving, is:—

Amsterdam	12 florins 3 stivers.	for £1
Hamburg	13 marks 12 schillings	
Paris	25 francs 50 cents	
Frankfort	121 Zollverein florins	
Vienna	10 florins 2 kreutzers	
Genoa	25 lire 35 centesimi	
Berlin	6 dollars 25 silver groschen	
Leghorn	30 lire Toscano 50 centesimi	

In giving

Lisbon	1 pence	for 1 milrea.
Madrid	"	1 hard dollar.
Gibraltar	"	1 hard dollar.

EXCHANGE, RATE OF

Naples	29½ pence	for 1 ducat.
Venice	47 "	" 6 lire Austriache.
St. Petersburg	86½ "	" 1 silver ruble.
Rio Janeiro	30 "	" 1 milrea.
New York	47½ "	" 1 dollar.
Calcutta	28 "	" 1 rupee.

See, for full information on the practical system of exchanges, Tate's *Modern Cambist*, from which work the foregoing rates are taken.

The rates of exchange as given above indicate what will be the proportion between the currency of any two countries when no exceptional circumstances arise to disturb the equilibrium of money values. In effect, however, rates are constantly oscillating in slight degrees above or below the precise proportions given. These oscillations are due partly to circumstances affecting the price of bullion in different countries, partly to the necessity for transmitting specie in liquidation of obligations from one country to another.

Thus when in any country two kinds of currency, gold and convertible paper, are simultaneously in circulation, the rate of exchange between this and another country will oscillate within narrow limits on either side of the proportions given above, a slight premium levied on the paying country being required by the broker who undertakes the business of liquidating obligations on commission; this premium being subject, by the competition of the market, to the fullest effect of all the influences which tend to increase or diminish the rate. Where, however, the circulation consists of inconvertible paper, the value of this currency will not only be liable to the disturbances consequent upon the varying market value of the paper, but also to the contingency of variations at the time when the paper is due. Thus the rate of gold in the United States and the rate of exchange with England differ considerably, the value of United States' currency being much lower according to the latter than according to the former estimate. In reality, of course, exchanges between country and country are effected in that which all nations will receive, the precious metals, though for convenience' sake they are expressed in the currency of the country in which the bill is ordered to be paid.

The business of negotiating foreign bills of exchange is chiefly in the hands of brokers, who know by means of certain simple calculations what is the rate at which they can consent to undertake the function in question, and the best means by which they can effect the exchange with the greatest profit to themselves, and who are of course fully alive to all circumstances which increase or diminish the competition for the service they render. For when a person has to remit a sum of money to another country, he does not seek out a person who has to receive a sum from that country, but is furnished by a broker with a bill, which has very likely been purchased by the broker the same day from some other customer. If the amount of business done between two countries is exactly equal, the liquidation of all transactions will be effected by the mere transmission of bills. If,

EXCHANGES, FOREIGN

however, it be more in one case than the other, the rate of payment made to the broker rises, in order that he may cover the charge of carriage and insurance in the transmission of specie, or the larger labour of a circuitous liquidation. In this case bills on the foreign country are at a premium, because more are wanted than are given in return. When, however, more are offered to brokers than are sufficient to cover those which they have to grant, bills are at a discount, and the price of the security as estimated by the premium charged on commission will fall. When, therefore, bills are at a premium in one country, they are at a discount in another, and vice versa.

It does not indeed always follow, because there exists a necessity for paying a balance of specie to one country, that specie will necessarily be exported for that purpose. The obligation may be temporary, and speedily covered by the creation of a debt per contra. The existence of a necessity to export specie is equivalent to a stimulus to exportation generally, and a discouragement on importation. Hence where the disagreement between the value of commodities bought and sold in any two countries is casual or temporary, the amount in excess due to one country is liquidated by bills created to meet the quantity of commodities exported in order to meet the excess in question. But a different state of things ensues when the cause inducing what is called an unfavourable state of the exchanges is permanent, or when there is an expectation that great and immediate money payments must be made. We shall advert below briefly to the state of things which ensues from these and similar phenomena under the head of **EXCHANGES, FOREIGN**.

For the sake of convenience, we have treated exchanges hitherto solely from a simple or hypothetical case; that, namely, which considers all exchanges as carried on between two countries only. But it will be remembered that the whole exports of a country, in whatever direction they go, pay for its whole imports, and that therefore exchanges and their rates do not depend on the amount of goods transmitted to countries separately, but on all taken together. England may owe a balance to France, but hold debts due to herself on Hamburg; and in this case, the debt due to France may be met by bills drawn on Hamburg. This method of meeting obligations is called the *arbitration of exchange*.

Exchanges, Foreign. The process of liquidating obligations created between different communities or governments does not differ in any of its principles from those which regulate the traffic in bills of exchange between different towns within the same community; but it is affected by particular or special circumstances, to such an extent as seemingly to put the trade in foreign bills into a totally different category from those of home circulation. When it is remembered that the trade in money, or securities representing the worth of money, by expressing quantities of money, is liable in the

fullest sense to competition, to the effect of supply and demand, and to other cognate economical forces, it will be clear that circumstances which tend to produce oscillations in market rates will apply with the greatest significance to the trade in foreign bills, because greater latitude is given in such securities for the influence of these exceptional events.

When all the accounts of a country with any other country are balanced evenly, so that values on both sides exactly correspond, they will be written off against each other, and the exchange will be at par. Such a state of things, however, is only hypothetically conceivable, for no accounts between country and country represent an exact equality. In the case of inequality, as has been said above, the rate is arbitrated by the interposition of bills drawn on other countries where a similar inequality prevails, due to the fact that in these the ratio is reversed; that is, that a greater indebtedness existing, a larger right to payment exists. Here, however, the first element of variation arises.

The standard of payment in this country is gold; in almost every other country it is silver. In every country but our own where gold is current, silver is similarly current; that is, where gold is a legal tender, silver is also. It now becomes necessary not only to consider what is the rate at which the liquidation can be effected, consequent on the greater or less amount of bills for sale, but what is the proportion which one form of currency bears temporarily to another; in other words, the foreign exchanges are virtually bullion transactions, and the rate of exchange being controlled by the *contingent necessity of exporting specie in liquidation of claims*, the question as to what means must be adopted for securing the presence of that metal in which payment must be made will materially affect the rate of exchange.

Again, the exigencies of a particular year or of a particular demand may cause that the balance of payments may be continuously adverse to any country. A bad harvest may necessitate a large purchase of corn; a rise in the price of some raw material of great importance may so disturb the market as to necessitate large purchases on account of manufactures; the exportation of large quantities of capital for foreign investment may necessitate a large efflux of specie, or, what is practically the same thing, may compel exports at lower prices; an engagement in the production of an article of great value, but of deferred supply, as of some particular crop, may compel the negotiation of securities with a view to bridging over the interval between production and sale; a panic felt at the approach of a commercial crisis may necessitate the holding of large quantities of the metallic currency in order to secure commercial safety; and these among other causes bring about that traffic in bills of exchange which implies what is called an unfavourable state of the foreign exchanges. As the rate at which bills are negotiated may under these circumstances approximate to the cost of

transmitting specie, but can never exceed it, the occurrence of any among these economical phenomena may lead to exportation of specie, continued till the cause which gives rise to it is met by a diminution of the cost of transmitting specie to the cost of transmitting bills. Anything, in short, which induces that state in which the charges of a community exceed its ordinary productive powers, will lead to an adverse exchange, and therefore diminish the metallic currency, either by liberating a portion of what has been hoarded or by drawing upon the reserves of banks.

The expression *adverse* or *unfavourable exchange* is a tradition of the time in which it was held to be an economical axiom, that the governments of such countries as are not producers of the precious metals should do all in their power to facilitate the importation, and retard or hinder the exportation, of gold and silver. At the present time, it is known that gold and silver are commodities, produced, exported, imported, or retained for special ends and for these alone, and that in ordinary times so much of them is retained for the use of a community as is absolutely needful, and no more. Hence in such communities as our own, in which money is made to set in motion as much commercial machinery as is possible, the quantity retained always tends to a minimum amount.

When, therefore, any events in foreign commerce occur which render necessary the payment of specie beyond the balance of goods, even though the diminution in the circulating medium be small, the effect is instantly apparent on the money market. The metallic currency possessed by a country is the power by which all commercial processes are set in motion, in the same way as the various machines in a great factory are impelled by the motion of a single rod in a steam engine, the force of the engine being, in order to avoid waste of power, exactly proportioned to the work it has to do. If, however, any portion of this force be subtracted or diverted, what remains is no longer adequate to perform the functions previously carried out; so if the currency sufficient to sustain the ordinary transactions of a community is suddenly diminished, some part of the gear must be slackened, or some of the machinery must lie idle, or some expedient adopted in order to recover what has been lost. Thus it follows that the amount of accommodation in discounts must be contracted by raising the rate at which the aid is given, and attempts must be made to right matters by an excess of exportation and a diminution of importation, that is by a process the reverse of that by which the drain of bullion was caused.

The effect of an adverse state of the exchanges is therefore twofold. It abstracts a commodity never kept, if possible, in excess, and so diminishes a necessary supply, while it also renders the means which on hypothesis underlie all commercial transactions and express all commercial obligations, more difficult to get at,

because more the subject of competition. Part of these results are natural, and derived from purely economical considerations; part are adventitious, and the result of the legislation of 1844, in the Bank Charter Act of Sir Robert Peel. The first of these results has its natural corrective in the readiness with which foreign capital is imported into a country in which a high rate prevails, by the inducement afforded from a high rate of interest; but the latter, by reason of the rigid and artificial character of the Bank restrictions, is less susceptible of remedy, and has been met on two occasions by the suspension of the conditions which form the basis of the Act itself, that is by granting the Bank permission to issue in excess of the amount allowed by the Act, and by giving the government guarantee of a bill of indemnity.

The subject of foreign exchanges has been lately discussed with great exactness and clearness by Mr. Göschel, to whose able scheme on the subject the reader may be referred.

Exchequer Bills. These are virtually bills of exchange issued by government in anticipation of revenue, and on the confidence of the annual financial income. They bear interest at a fixed rate, this rate being computed at the time of their issue, at a sum proportioned to the current market rate, the fluctuations in the value of these securities depending on the proportion which such a rate bears to successive changes in the market price of money: when this is high, the security being at a discount; when low, at a premium.

The origin of exchequer bills is to be referred to the earliest period of systematic finance of England; to the consequences, namely, of the Revolution of 1688. At this time, the success of the political changes effected in Great Britain was closely identified with the maintenance of public credit, although (as might be expected, at a crisis when financial expedients and the machinery of commerce were experimental and dubious) confidence was capricious and feeble. Banking on any systematic and large scale was in its infancy, and its principles were imperfectly recognised. The currency was in a most degraded condition, the nominal value of silver coin being nearly double that of its actual weight, while the nation was staggered with the magnitude and weight of its expenditure, as well as bewildered by the apparent insecurity of its new institutions, and the notorious disaffection of a large portion of the aristocracy and landowners to the new establishment.

The first issue of exchequer bills, in 1696, was suggested by the financial genius of Mr. Montague, and was in aid not so much of the revenue as of private credit, by supplying a substitute for the currency, which at that time had reached its lowest point of degradation and was being reformed. The effect of the issue was most salutary. The bills were eagerly received as currency, having been issued in very low sums, and contributed more to put trade on a sound footing than anything else.

EXCHEQUER CHAMBER

Since that year, exchequer bills have been annually issued, and now form a regular portion of the annual supply, and of an annual vote, the amount and the rate being yearly determined by Act of Parliament.

Exchequer bills are a convenient form of investment in banking and other analogous establishments. There is a security that the amount designated in them will be repaid in full with interest, low indeed, but determined by the market, and commensurate with the conveniences of this form of investment. They are receivable in payment of taxes, and therefore pro tanto at least, are an annual addition to the currency. The interest paid on exchequer bills in the years 1860-1, 1861-2, 1862-3 respectively was 300,087*l.*, 478,400*l.*, 371,917*l.* and on exchequer bonds 100,000*l.*, 122,500*l.* 123,700*l.*

Exchequer Chamber, Court of.

Law, this court is, by 1 Wm. IV. c. 70, constituted the proper tribunal for the trial of writs of error from the three superior courts of common law. In this court the writ is tried before the judges, or judges and barons, of the two courts which had not given the former judgment. Error from this court lies in the House of Lords, which is the last and highest appellate tribunal of the country.

Exchequer, Chancellor of the. [CHANCELLOR OF THE EXCHEQUER.]

Exchequer, Court of. In Law, a court originally established for the recovery of the king's debts and ordinary revenues of the crown. In its modern shape, it is in fact a combination of eight distinct ancient courts. It acquired concurrent jurisdiction with the other two superior courts in all personal actions [COURTS SUPERIOR] by the fiction of the complaining party being debtor to the king; a fiction which is now removed. It has exclusive jurisdiction in cases in which the king's revenue is concerned, whether personal actions or informations filed under the various revenue Acts. It had formerly also an equitable jurisdiction, abolished by 5 Vict. c. 6. [CHANCELLOR.] The chief and four puisne or younger judges of the Exchequer are termed *barons*.

EXCHEQUER, COURT OF (in Scotland). This court, established by 6 Anne c. 26, properly consisted of a chief baron and four junior barons; but three only were commonly appointed. It had a jurisdiction as to duties of customs, excise, and other revenues of the crown. It was abolished in 1832.

Exchequer Tallies. One of the earliest and most lasting methods of checking accounts was by the use of tallies, which formed a rude but effective form of indenture. Hazel wands were provided, into which notches denoting different amounts were cut, and the rod was split, one half being retained by the office, the other held by the creditor of the exchequer. When presented for payment, the tallies were compared; and of course fraud was made difficult, if not impossible. A similar system lingered even yet in some rural districts and

EXCISE

towns in the sale of milk and beer; one half of the stick being kept by the purchaser, the other by the seller, and fresh credits on account of the latter being entered by laying the sticks together and notching them. It is stated, especially in the trade between brewers and publicans, that the check afforded by this method against fraud in the trade is far more effectual than by the modern substitute of mutual account-books, and that the abandonment of the system has been an inconvenience.

The cancelled tallies of the exchequer accumulated to a vast amount, and an order was at last given for their destruction. It is said that, in consequence of a too liberal use of these wooden records, the houses of parliament were destroyed on the night of October 16, 1834.

Excise (Fr. from Lat. *excido*, *I cut or clip off*). The levy of duties on home manufacture intended for consumption within the country is said to have been one of the expedients adopted by the United Provinces of Holland during their struggle to achieve their political independence. It entered into the fiscal scheme of the Long Parliament in the year 1643, the tax being levied at first upon all beer and ale brewed. The king's parliament at Oxford imitated the action of the house at Westminster, and exacted, as far as possible, duties within the limits in which the king's authority was respected. Excises were continued during the Protectorate, though the impost was exceedingly unpopular.

At the Restoration, according to the principles laid down by the lawyers of the period, who held that, as Cromwell had not been king, the Act of Henry VII., giving validity to the laws passed by *de facto* monarchs, did not apply to the statutes of the parliamentary regime, the feudal liabilities of the tenants in capite revived. The grievance of these liabilities was no doubt intolerable, and, as the preamble of the Act 12 Ch. II. cap. 24 expressed it, 'much more burdensome, grievous and prejudicial to the kingdom, than beneficial to the king.' But the remedy provided was not, as might have been expected, the levy of a land tax in accordance with a scheme proposed in the reign of James I., but the substitution of an hereditary excise on ale and beer, cider, perry, mead, spirits, coffee, tea, sherbet, and chocolate; in other words, the landowners of the period emancipated their own estates at other people's expense. From this time the excise became a permanent feature in English finance; the revenue derived being settled, up to the Revolution, on the king for life.

Under the wild system of taxation which prevailed during the eighteenth and part of the nineteenth centuries, no administration dreamed that the imposition of tax upon tax, excise upon excise, for the purpose of securing funds on which loans might be based, could ever fail to bring the revenue contemplated at the time in which the impost was created, or troubled itself about the effect likely to be

EXCITABILITY

produced on industry by the introduction of the cumbersome, expensive, and vexatious enactments comprised under the general mass of excise Acts. Hence, while almost every conceivable article manufactured in England was made liable to an excise, and with it to hindrances to improvement, and the arbitrary interference of government officials, the administration actually levied duties on consumption upon those articles which already bore a customs duty on importation, and was perpetually lost in admiration at the miscalculations made as to the produce to the revenue of the impositions in question. The sole objects of governments, in short, was to get money; and the almost universal consequence of the expedients they adopted was to fail in procuring what they desired, and to succeed in cramping, distorting, or otherwise damaging the industrial energies of the community.

The chief inconvenience in an excise is that it generally interferes with the adoption of such processes as tend to diminish the cost of production. The officers appointed to supervise the production of excisable articles must needs have continual access to works in which the commodity is made; and as they are supposed to be perpetually on the look-out against the contingency of fraud, they are sure to object to mechanical or other improvements in the manufacture, on the ground that they have a tendency towards defrauding the revenue, even if, in the face of perpetual supervision, the manufacturer felt disposed to improve his process.

In accordance with the sounder theories of modern finance, the levy of an excise duty is limited to a few articles in universal consumption; and the system of bonding excisable articles is adopted as fully as in the importation of articles liable to a customs duty. Since the year 1861, the excises on bricks, soap, paper, and hops have been repealed, to the great advantage of the public. At present, the only articles chargeable with excise in the United Kingdom are malt, spirits, sugar, and chicory, the last two being very unimportant; and a powerful agitation, hitherto indeed unsuccessful, has been instituted with a view to the abolition of the excise on malt. Notwithstanding these reductions, however, the amount of revenue derived from the excise has largely increased since the period at which these reforms began; for instance, the gross proceeds of the excise in 1864 were eighteen and a quarter millions as compared with fifteen millions in 1860.

Excitability (Lat. *excito*, *I rouse*). A disposition to be affected by exciting causes. It is a term chiefly used in Medicine, in reference to that state of system which is more or less susceptible of morbid excitement.

Excitants (Lat. *excito*). Medicines which excite the actions of the system: they are either general, such as alcoholic liquors, &c., or local, such as diuretics, diaphoretics, &c.

Excito-motor Acts. In Physiology, this term has been applied to the first class

EXCREMENTS

of nervous actions defined as those sensory vibrations which are excited in the external organs and ascend towards the brain, when they arrive in their ascent at the origins of motor nerves. These, arising from the same common trunk, plexus, or ganglion, with the sensory ones affected, detach a part of themselves at each of those origins down the motory nerves; which part by agitating the small particles of the muscular fibres excites them to contraction. 'The actions of sneezing, swallowing, coughing, hiccupping, vomiting, and expelling the feces and urine, with others of a like nature, are to be deduced from the first and fourth classes of motor vibrations; i.e. either from those vibrations which first ascend up the sensory nerves, and then are detached down the motory nerves, which communicate by some common trunk, plexus, or ganglion; or else from those vibrations that run along the surfaces of uniform membranes, and so affect all the muscles which lie contiguous to any part of the membranes.' (Hartley *On Man*, p. 97.) 'The yawnings and stretchings of persons disposed to sleep, the convulsive respiration of those that are just fallen asleep, and the convulsive motions which attend the extinction of the senses in epileptic fits, and the near approach of death, may be derived, perhaps, in part, from this source.' (Ib. p. 93.) [MOTOR AND REFLEX ACTION.]

Exclusion, Bill of. In English History, a bill introduced into parliament during the reign of Charles II. for the purpose of excluding the duke of York from the throne, as being a Papist.

Excommunication (Lat. *excommunicatio*). An ecclesiastical censure, by which a man is cut off from communion with his church. In the forms of excommunication of the Greek and Romish churches, the excommunicated person is solemnly devoted to the power of evil. The English church retains a form of excommunication, in cases of adultery, incontinence, heresy, simony, and neglect of public worship, &c.; the practice, however, has long become obsolete. In English law, excommunication was the ordinary mode by which contempt of the ecclesiastical jurisdiction was punished and its process enforced. Forty days after sentence the writ *de excommunicato capiendo* issued (called also a *significavit*, from the recital of the bishop's certificate with which it commenced), under which the party was apprehended by the sheriff. By stat. 53 Geo. III. c. 127, the legal effect of excommunication was abolished, and the writ *de contumace capiendo* substituted for the former one. Since the transfer of the chief branches of ecclesiastical jurisdiction to other courts, it has become virtually obsolete.

Excoriation (Lat. *ex*, and *corium*, *skin*). An abrasion of the cuticle.

Excrements (Lat. *excrementum*). Matters discharged from the intestinal canal. Their chemical composition has some important bearings on physiological questions and on their

EXORETINE

application as manures. (*Watt's Chemical Dictionary*, art. 'Excrements'.)

Exoretine (Lat. *excerno*, *I separate from*). A name given by Marcet to a crystallisable substance extracted from faeces. (*Phil. Trans.* 1854.)

Excretories. The ducts which convey the secreted fluids from the glands.

Excurent (Lat. *excurrens*, *running out*). In Botany, a term used in describing the ramification of any body whose axis always remains in the centre; the other parts being regularly disposed around it, as the stem of *Abies excelsa*.

Execution (Lat. *executio*, *an accomplishment*). The carrying into effect of the judgment given in a court of law. This is performed in different manners according to circumstances; in a common action for debt or damages, the successful plaintiff may either arrest and imprison the body of the defendant under a writ of *capias ad satisfaciendum*, or may have execution against his goods under a *fieri facias*, or against his lands under an *elegit*. There are other modes of enforcing payment in cases to which these remedies do not apply. In criminal cases execution takes place by direction of the judge who tries the prisoner, given by his entering on the calendar a memorandum of each sentence.

Excursion. In the Fine Arts, the mode of performing a work of art, and the dexterity with which it is accomplished. The Dutch and early Flemish schools have hitherto attained the highest proficiency in execution.

Executive. In the theory of Government, that part of the powers of the state which is employed in putting into execution the laws made by the legislature or the decrees of the judicial power. In England, all executive power is supposed to be vested in the queen, and in inferior officers by her delegation.

Executor (Lat. *executor*, *one who performs*). In Law, an executor is a person appointed by a testator (the appointment being confirmed by the Court of Probate) to execute his will, and to represent him in his personal rights and liabilities. Thus, the rights and liabilities of an executor in his representative capacity (the same as those of an administrator) are those of the testator or intestate, arising for or against him—either out of contract, or from injury done to his property, real or personal, or from injury done by him to the real or personal property of another; but the liabilities of an executor or administrator do not overreach the property or assets which he has received, or might, but for his negligence or default have received, by virtue of his office.

The first and most important duty of executors and administrators is the payment of debts which attach to the property in their hands, in the following order (the reasonable expenses of the funeral, and the necessary expenses of proving the will, or of obtaining letters of administration, being first defrayed):—

1st. Debts due to the crown by record or on specialty.

EXECUTOR

2ndly. Debts due to the subject by virtue of the judgment of any court of record.

3rdly. Debts acknowledged upon record, as by recognisance.

4thly. Debts due upon specialty, or on account of rent.

5thly. Debts of the crown not upon specialty or record.

6thly. Debts by simple contract.

Creditors of each class are entitled to be paid in full before anything is allowed to debts of an inferior order; and as between themselves they are paid pro rata as far as the assets will extend. But an executor will be allowed, upon account, any debt that he may have paid without notice of another debt of a higher class: and as between creditors of equal degree, he may, before action brought at law, or decree to account in equity, give preference to any. He may also at any time as against creditors of an equal class retain a debt due to himself.

Next to debts stand, in the first place, specific legacies, i. e. gifts of specific parts of personal estate; and in the next place general legacies, that is, gifts of money payable out of the general residue of such estate: what remains after payment of legacies, where there are any, or, where there are none, after payment of debts, is divisible among the next of kin according to the Statute of Distributions. Specific legacies may be recovered at law; but the rights of general legatees, and of next of kin, are enforceable only in courts of equity or in the ecclesiastical courts.

Most frequently also claims in the nature of debt or legacy to which the personal estate of testators or intestates is subject are prosecuted in courts of equity, which not only, like courts of law, take cognisance of each individual right as brought forward, but will take upon themselves the whole administration of the estate and retain it in their hands for the purpose of doing justice to all claimants.

In so doing, courts of equity are bound to follow the legal order of priority above stated, so far at least as the assets are legal; i. e. either recoverable in courts of common law, or those which otherwise come to the executor by virtue of his office. There are, however, assets for which the remedy of the creditor lies in a court of equity. These are known by the name of *equitable assets*, and in the application of such assets the rule obtains of equality between all debts, the priority of debts to legacies, and among these of specific to general, being still observed. Where there are both legal and equitable assets, creditors availing themselves of their priority against the legal assets will not be admitted to any participation in the equitable assets till other creditors shall have received out of them the same proportion of their debts as shall have been already paid to the creditors of a higher degree out of the legal assets.

By 3 & 4 Wm. IV. c. 104 real estate not devised for or charged with the payment of

EXEGESIS

debts is made assets for the payment of all debts, to be administered by courts of equity according to the legal order of priorities; but real estate so devised or charged still remains, as before, equitable assets. Executors and administrators, as such, have no concern in either case with the application of real assets.

Many questions arise in regard to legacies as to when they are vested, when specific or general—which it is impossible to notice within the limits of this summary.

Exegesis (Gr. *explanation*). The term applied most usually to the exposition or interpretation of the Holy Scriptures; it is also used, however, in an unrestricted sense.

Exergue (Fr.). In Numismatics, the basis or lower limb of a coin or medal, when separated by a line from the rest of the face, which usually contains words giving the date, place, &c. of the coin, or other subsidiary matter. [NUMISMATICS.]

Exfoliation (Lat. *folium, a leaf*). The separation of a piece of dead bone from the living, as of leaves from a tree.

Exhalation. [VAPOUR; EVAPORATION.]

Exhaustion (Lat. *exhaustio, I draw out*). An ancient geometrical method which has been replaced by the modern differential calculus. The ancients employed this method in their difficult researches, particularly in the theory of curve lines and surfaces, and in determining areas and volumes. As they admitted no demonstrations but such as are perfectly rigorous, they did not consider curves as polygons of a great number of sides; but in attempting to discover the properties of any curve, they regarded it as the fixed term or limit to which the inscribed and circumscribed polygons continually approach, and approach the nearer as the number of their sides is increased. Thus they *exhausted*, as it were, the space between the polygons and the curve; and hence this method of procedure was called the *method of exhaustion*. When the properties of a curved line or surface were thus divined, however, it was usual to give an indirect geometrical demonstration of them, by showing that every contrary hypothesis must necessarily lead to a contradiction or absurdity.

Exhedra (Lat.; Gr. *ἔξεδρα*). In ancient Architecture, a small room in the baths and other buildings appropriated for conversation. The name was especially applied to the hall in Pompey's theatre at Rome.

Exheredation (Lat. *exheredatio*). In the Civil Law, the exclusion of a child from inheriting any part of his father's estate. (Sandars's *Justinian*, 278.)

Exhibit (Lat. *exhibitus*, part. of *exhibeo, I show*). In Law, any paper produced in a court of law or equity; or in the latter referred to in affidavits and certified.

Exhibition. A term applied in modern times to the public display of works of art. This word is also used to denote private benefactions instituted for the maintenance of scholars in the universities. [BURSARS.]

Exigi Facies or **Exigent**. In Law, a

EXOPHTHALMIA

writ which, since the abolition of outlawry on mesne process, is only used for the purpose of proceeding against a debtor to outlawry on final process. [OUTLAWRY.]

Exile (Lat. *exilium*). In Roman law, the punishment of banishment, or, more strictly speaking, the consequence of the interdiction from the use of fire and water, pronounced as a sentence against great offenders, compelling them to expatriate themselves. It appears that the direct sentence of exile was not known to ancient Roman jurisprudence. (Cicero *ad Herenn.*) In modern France (before the Revolution), there was a distinction between banishment and exile. The former was a punishment assigned by the law, and producing infamy; the latter a measure of discipline, inflicted by the arbitrary act of the monarch (usually through *lettres de cachet*). Thus political offenders were frequently exiled to their estates, to a certain distance from court, &c.

Exintine (Lat. *ex, from, and intus, within*). In Botany, a membrane situated between the extine and intine in the pollen of yew, juniper, cypress, &c.

Existence. [PERCEPTION; MATERIALISM.]

Exocetus. [FLYING FISH.]

Exochinata. A designation of the long-tailed *Crustacea*; as the lobster and shrimp.

Exodium (Gr. *ἐξόδιον*, from *ἐξοδος, a going out*). In Greek Tragedy, the final chorus of a play. At Rome, the *exodia* were burlesques acted after other plays.

Exodus. [PENTATEUCH.]

Exogenous. In Botany, growing by additions to the outer surface of the stem, as in the case of our European timber-trees.

Exogens (a word coined from Gr. *ἔξω, without, and γίνομαι*). One of the primary classes into which the Vegetable world is divided. It is characterised by having the leaves reticulated; the stems with a distinct deposition of bark wood and pith; the embryo with two cotyledons; and the flowers usually formed on a quinary type. A transverse slice of the stem exhibits a central cellular substance or pith, an external cellular and fibrous ring or bark, and an intermediate woody mass, with certain fine lines radiating from the pith to the bark through the wood, called *medullary rays*. They are called *Exogens* because they add to their wood by successive external additions.

Exogonium (Gr. *ἔξω, and γόνυ, a knee*). A genus of *Convolvulaceae*, comprising the plant which yields Jalap. This plant, a native of Mexico, is called *E. Purga*, and is a climber, with cordate ovate leaves, and pretty salver-shaped purplish flowers, having a long, straight, slender tube. The Jalap roots of commerce are roundish dark-coloured bodies of variable size, and owe their purgative properties to the resinous ingredients in their composition. [JALAP.]

Exomphalos (Gr.). A hernia or rupture at or near the navel.

Exophthalmia (Gr. *ἔξω, and ὀφθαλμός, the eye*). The protrusion of the eyeball from the

EXOPHYLLOUS

orbit. It is usually the consequence of concussions or blows; sometimes it is produced by a tumour in the orbit, which gradually pushes the eyeball out of its socket.

Exophyllous (Gr. *ἔξω*, and *φύλλον*, a leaf).

A term applied to the young leaves of Exogens, since they are said to be always naked, while those of Endogens sheathe each other.

Exoptiles (Gr. *ἔξω*, and *πτερόν*, a feather).

A term for Dicotyledonous plants, because their plumula is naked.

Exorcism (Gr. *ἐξορκισμός*). The solemn adjuration by which those endowed with certain powers were believed to subject evil spirits to their obedience: more particularly to compel them to leave the bodies of those supposed to be subject to demoniacal possession. The exorcists form one of the minor orders in the church of Rome.

Exordium (Lat. *a beginning*). In Oratory and Literature, the opening part of an oration.

Exorrhizæ (Gr. *ἔξω*, and *ρίζα*, a root). A term applied to the embryo of Dicotyledons; inasmuch as their radicle always elongates downwards, directly from the outside of the base of the embryo.

Exosmose (a word made up from Gr. *ἔξω*, and *σμός*, impulsion). The passage of gases, vapours, or liquids through membranes or porous media from within outwards. M. Dutrochet found that if two fluids of unequal density are separated by an animal or vegetable membrane, the denser will attract the less dense through the membrane that divides them: this property he called *endosmose* when the attraction is from the outside to the inside: and *exosmose* when it operates from the inside to the outside of the body acted upon. [ENDOSMOSA.]

Exostome (Gr. *ἔξω*, and *στόμα*, a mouth). In Botany, a term invented to denote the passage through the outer integument of an ovule, commonly called the *foramen*.

Exostosis (Gr.). In Anatomy, a swelling or tumour of a bone.

Exostosis. In Botany, a disease to which the roots and stems of trees are subject, when knots or large tumours are formed upon or among the wood. It is caused by a stoppage of growth on the one hand, and an attempt at excessive development on the other. It is from sections of the exostoses of trees that some of the most beautiful wood used by cabinet-makers is obtained. These knots are sometimes called *knaws*.

Exostra (Gr. *ἐξόστρα*). In ancient Architecture, a machine for representing the interior part of a building, as connected with the scene of a theatre.

Exostrea. In ancient Military art, a bridge thrust out of a turret upon the wall of a town, by which the besiegers obtained an entrance.

Exoteric. [ESOTERIC.]

Exothecium (Gr. *ἔξω*, and *θήκη*, receptacle). In Botany, that portion of an anther from which the pollen is incorrectly supposed to separate; it is the coating of the anther.

EXPANSION

Exotic (Gr. *ἐξοτικός*, foreign). Anything introduced into one country from some other country. In Gardening, it is sometimes applied to plants which require protection in winter, or to plants in general which are not European.

Expansion (Lat. *expando*, *I open out*). One of the most common and obvious effects of heat, which expands or enlarges the bulk of all the forms of matter. The expansion of solids by increase of temperature is comparatively small; but it may be rendered sensible by carefully measuring the dimensions of any substance when cold, and again when heated: an iron bar, for example, fitted to a gauge, which shows its length and breadth, will no longer pass through the apertures when heated. Among solids the metals are most expansible and contractile by heat and cold; but they vary much in this respect, as shown in the following table, which exhibits the change of dimensions which several of them undergo when heated, from the freezing to the boiling point of water:—

	Temperature	
	32°	212°
Platinum . . .	120,000	120,104
Steel . . .	—	120,147
Iron . . .	—	120,151
Copper . . .	—	120,204
Brass . . .	—	120,230
Tin . . .	—	120,290
Lead . . .	—	120,245
Zinc . . .	—	120,360

The average expansion of glass is very nearly the same as that of platinum.

The expansibility of different liquids is also very variable; ether for instance, and alcohol, are more expansible than water, and water more than mercury. The expansibility of mercury is applied to a very useful purpose in the construction of the common thermometer.

In general, all liquids expand and contract in proportion as they are heated and cooled; but to this law there is a remarkable and anomalous exception in regard to water. When a large thermometer tube is filled with water of the temperature of 60°, and placed in a cold situation, or in a vessel filled with pounded ice, the water goes on shrinking in the tube till it has attained the temperature of about 40°; and then, instead of continuing to contract till it freezes (as is the case with other liquids), it slowly *expands*, and actually rises in the tube until it reaches the freezing point. In this case, the expansion above 40° and below 40° seems to be equal; so that water will be of the same bulk at 48° and at 32°. This anomalous expansion of water by cold is productive of some important consequences, considered as a natural operation; for if water, like other fluids, went on increasing in density till it froze, the consequence would be that large bodies of water, instead of being only superficially frozen in winter, would be converted throughout into solid masses of ice. Let us take a fresh-water lake as an example. The earth being in winter

EXPANSION GEAR

warmer than the air, the heat is withdrawn from the surface of the water by the cold breezes that blow over it; and the whole body of water has its temperature lowered to 40° , which is the point of its greatest density—a temperature perfectly congenial to fish and most other aquatic animals. The cold now continues to operate upon the surface of the water; but, instead of diminishing its bulk, and therefore rendering it heavier than the warmer water beneath, the cold expands it, and renders it lighter; so that under these circumstances a stratum of ice-cold water (at 32°) will be found lying upon the mass of warmer water beneath it (at 40°). The influence of the cold continuing, the surface of the lake will soon freeze, but the water immediately below the superficial covering of ice will be found comparatively warm; and as water is almost a non-conductor of heat, it will be a long time before the ice attains any thickness; and the whole body of water, if of any depth, can never freeze throughout. Indeed, it will be obvious that the retardation of freezing will be proportional to the depth of water which has to be cooled; and hence some very deep basins or lakes are under ordinary circumstances scarcely ever even covered by ice.

As liquids are enlarged and consequently rendered specifically lighter by heat, very different effects are produced by applying heat to different parts of the vessels containing them. If the heat be applied to the bottom of the vessel, the liquid is soon heated equally throughout, and made to boil; but if the surface only be heated, it may then be boiled and evaporated, while the lower parts remain quite cold.

Aëriform bodies and vapours are the most expansible forms of matter, and they present an important peculiarity; for in other substances each individual has its own degree of expansion and contraction, whereas all aëriform bodies expand and contract alike; so that if we accurately determine the expansion and contraction of any one of them, that knowledge applies to all the rest. 100 measures of air when heated from the freezing to the boiling point of water, suffer an increase of bulk equal to 37.6 parts; so that 100 cubic feet of air at 32° become dilated to $137\frac{1}{2}$ cubic feet at 212° .

Expansion Gear. The machinery fitted to an engine for the purpose of cutting off the steam at different portions of the stroke, according to the amount of work required to be effected by the engine. The steam in these cases is allowed to enter the cylinder at the pressure under which it is generated; it is then cut off, at the portion of the stroke the engineer thinks fit; and finishes the stroke by its natural expansion. Sometimes the term *expansion joints* is applied to such joints as are made with a stuffing-box or an elastic junction on their length, which will allow them to expand freely under the effects of the alteration of temperature to which they may be exposed by the passage of steam through the pipes.

EXPECTATION OF LIFE

Expectation of Life. By this term writers on annuities and reversions express the mean duration of human life, after a specified age, according to a given table of mortality. With regard to an individual of a given age, the *expectation of life* is the mean number of future years which individuals of that age, one with another, actually live. The *expectation of life*, according to this definition, differs altogether from what is called the *probable life*. The latter term denotes the period at the end of which the probability of being alive is equal to that of being dead, or is equal to $\frac{1}{2}$; and this is manifestly the period in which the number of lives in the table, beginning with any given age, is reduced to one-half. Thus, if in a given table of mortality we find that 1,000 individuals are living at the age of 40, and that of these 500 only are living at the age of 63, then the *probable life* of an individual aged 40, according to that table, would be 23 years; that is to say, it is an even wager whether he will be alive or dead at the end of 23 years. The *mean life*, or *expectation of life*, is, however, quite different in principle (though in most tables not very different in amount), and depends on the same mathematical probabilities of living over each future year of life, to the last in the table, as are employed in the calculation of life annuities. It is computed as follows:—

Let the probabilities that a life of a given age will live over

1, 2, 3, 4 . . . x years,
be p_1 , p_2 , p_3 , p_4 . . . p_x respectively;
then the probability that the life will fail in any given year x , is $p_{x-1} - p_x$.

Now, in computing the portion of existence which an individual may expect to enjoy in respect of any future year x , there are two contingencies to be considered: 1st. The individual may live over that year, in which case he will enjoy a whole year of life = 1. But the probability of this event is p_x ; therefore

$$p_x \times 1 = p_x$$

is the portion of time he may at present expect to live in respect of that year. 2nd. The individual may die in the course of that year; and as the chances of dying at any particular part of the year are equal, we must suppose him to die at the middle of the year; in this case, therefore, he enjoys half a year of life = $\frac{1}{2}$. But the probability that his death will happen in the x th year is $p_{x-1} - p_x$; consequently

$$\frac{1}{2} (p_{x-1} - p_x)$$

is the portion of time he may hope to live, in respect of that year, on the second contingency.

Adding the two results together, we get

$$p_x + \frac{1}{2} (p_{x-1} - p_x) = \frac{1}{2} (p_{x-1} + p_x)$$

for the whole of his expectation of life in respect of the x th year from the present. Substituting successively the numbers 1, 2, 3, &c. for x , in order to get the expectation for each succeeding year till the last age in the table, and denoting the sum of the expectations by E , we find (since $p_0 = 1$)

EXPECTATION OF LIFE

$$E = \frac{1}{2} (1 + p_1 + p_2 + p_3 + \&c.) \\ + \frac{1}{2} (p_1 + p_2 + p_3 + \&c.);$$

consequently,

$$E = \frac{1}{2} + p_1 + p_2 + p_3 + \&c. \dots (1).$$

Thus it appears that the true value of the expectation of life is equal to the sum of the probabilities of the life enduring through 1, 2, 3, &c. years to the limiting age of the table of mortality, increased by $\frac{1}{2}$. The labour that would be required to sum this series for every different age is avoided by deducing the expectation of one age from that of the next older, as is usually done in computing annuity tables. Thus, let E_1 denote the expectation of life for an individual one year older than the former, and let the probabilities of his living over 1, 2, 3, &c. years be respectively $q_1, q_2, q_3, \&c.$; then we must have

$$E_1 = \frac{1}{2} + q_1 + q_2 + q_3 + \&c. \dots (2).$$

But from the nature of the probabilities in question,

$$p_2 = p_1 q_1,$$

$$p_3 = p_1 q_2,$$

$$p_4 = p_1 q_3, \&c.$$

Substituting, therefore, these values in (1), we find

$$E = \frac{1}{2} + p_1 (1 + q_1 + q_2 + q_3 + \&c.) \dots (3).$$

Whence, on eliminating $q_1 + q_2 + q_3 + \&c.$, from the two equations (2) and (3), we get

$$E - \frac{1}{2} = p_1 (E_1 + \frac{1}{2}),$$

which is the most convenient form under which the formula can be put for computation.

For the explanation of the manner in which the probabilities $p_1, p_2, p_3, \&c.$, are determined from the ordinary tables of mortality, see ANNUITY.

The following table, from Mr. Milne's *Treatise on the Valuation of Annuities and Assurances* (vol. ii. p. 565) shows the expectation of life at every age, according to the law of mortality at Carlisle:—

Age	Expectation	Age	Expectation	Age	Expectation	Age	Expectation
0	38.72	26	37.14	52	19.68	78	6.12
1	44.68	27	36.41	53	18.97	79	5.80
2	47.55	28	35.89	54	18.28	80	5.51
3	49.82	29	35.00	55	17.58	81	5.21
4	50.76	30	34.34	56	16.89	82	4.93
5	51.25	31	33.68	57	16.21	83	4.65
6	51.17	32	33.03	58	15.55	84	4.39
7	50.80	33	32.36	59	14.92	85	4.12
8	50.24	34	31.68	60	14.24	86	3.90
9	49.87	35	31.00	61	13.59	87	3.71
10	48.82	36	30.32	62	12.91	88	3.59
11	48.04	37	29.64	63	12.21	89	3.47
12	47.27	38	28.96	64	11.50	90	3.28
13	46.51	39	28.28	65	11.79	91	3.26
14	45.76	40	27.61	66	11.27	92	3.27
15	45.00	41	26.97	67	10.75	93	3.45
16	44.27	42	26.34	68	10.23	94	3.53
17	43.57	43	25.71	69	9.70	95	3.63
18	42.87	44	25.09	70	9.18	96	3.66
19	42.17	45	24.46	71	8.65	97	3.28
20	41.48	46	23.83	72	8.16	98	3.07
21	40.75	47	23.17	73	7.72	99	2.77
22	40.04	48	22.50	74	7.33	100	2.28
23	39.31	49	21.81	75	7.01	101	1.79
24	38.59	50	21.11	76	6.69	102	1.30
25	37.86	51	20.39	77	6.40	103	0.83

EXPIATION

Expectorants (Lat. *expectorare*, to *expectorate*). Medicines which increase the secretion of the tracheal and bronchial mucus. The term *expectoration* is applied to anything cast off from those vessels or from the cells of the lungs by spitting or coughing.

Expectoration (Lat. *expectorare*). The act of ejecting matters from the chest. The term is sometimes applied to the matter ejected, which is, however, more properly termed *sputum*.

Expenditure (Lat. *expendo*, *I pay out*). In Finance, the charges levied annually on the community for the public service. The items of the public expenditure are generally tabulated under four great heads: 1. The interest and management of the public debt; 2. The civil list and civil charges of all kinds; 3. The forces; 4. The charge of collection.

Up to 1854 it was the practice to complete the financial year on the 6th of January. In this year, however, a change took place; and it was arranged for the convenience of the administration that the financial year should end on the 31st of March. As a rule, the expenditure of the country for the forthcoming year is the first duty of parliament in the vote of supplies, the budget of the Chancellor of the Exchequer being based upon the supply granted. If extraordinary expenses become necessary, a supplementary budget is prepared.

The following is the amount of gross expenditure for the last fifteen years:—

Years ended Jan. 5,	£	Years ended Mar. 31,	£
1850.	55,287,532.	1856.	92,986,737.
1851.	54,745,176.	1857.	76,042,570.
1852.	53,850,445.	1858.	68,128,859.
1853.	55,117,656.	1859.	64,663,883.
1854.	55,647,991.	1860.	69,502,289.
Qr. to April 5,		1861.	72,842,059.
1854.	14,012,164.	1862.	72,086,486.
Mar. 31,		1863.	70,352,008.
1855.	69,012,760.	1864.	67,856,286.

During the last four years 2,870,000*l.* have been raised for fortifications: on terminable annuities, this sum being included in the expenditure. Of the several charges enumerated above, the interest and management of the debt has diminished; while the expenditure for civil and military purposes has greatly increased.

Experimentum Crucis (Lat.). Bacon's *Crucial*, or *decisive* experiment (so called from the *crosses*, or finger-posts on roads), as at once determining between two or more possible conclusions.

Expiation (Lat. *expatio*). In its most extended meaning, the act by which a guilty person makes atonement to religion, morals, or society at large, for any crime or fault, whatever be its nature or extent. In most of the ancient religious systems the idea of expiation was confined to cases of blood-shedding; and its growth can be traced through the practice of compensation in money to a fixed ceremonial administered by kings or priests.

EXPIRATION

This ceremonial varied with the character of every nation and the nature of the crime which it was intended to expiate. Among the Greeks and Romans, expiations were sometimes made for whole cities. There is no mention of the practice of expiation for murder in the Homeric poems. (Grote's *History of Greece*, part i. ch. i.) [SACRIFICE.]

Expiration (Lat. *expiratio*). In Physiology, the movements by which the air that has been changed by the respiratory process is expelled from the lungs; they are chiefly due to the elastic contraction of the lungs and the walls of the chest, after they have been dilated in the act of inspiration.

Explicit Function. A variable is said to be an *explicit function* of several others when its value, expressed in terms of those of the independent variables, is given. Thus, if

$$s = ax^2 + 2bxy + cy^2,$$

s is said to be an explicit function of x . If on the other hand s were connected with x and y by an equation of any other form, it would be called an *implicit function* of the latter.

Explosion (Lat. *explosio*). In Natural Philosophy, a sudden and violent expansion of the parts of any object. Explosion differs from expansion in this, that whereas the former is always sudden, and only of momentary duration, the latter is the effect of some gradual and continued power, acting uniformly for some considerable time. [EXPANSION; MATTER, PROPERTIES OF.]

Exponent (Lat. *expono*, *I set out*). In Algebra, a number, or a symbol representing a number, which when written above and to the right of any symbol of quantity, indicates that a corresponding power of that quantity is to be taken. Thus a^3 denotes the *third power* of a , and 3 is said to be the *exponent* or *index* of that power; usually, though less strictly, it is called the *exponent* of a . Thus a^2 is merely an abbreviation for $a \times a$, and from the definition of an exponent it follows at once that $a^{m+n} = a^m \times a^n$. The notation of exponents was introduced by Descartes, and being extremely convenient was soon extended. The convention upon which the extension is based is the *general truth* of the last equation. Thus if we ask for the meaning of a negative or fractional exponent, on the hypothesis that the last equation shall hold for all values of m and n , we find that since

$$a^m = a^{m+n} = a^m \times a^n,$$

a^0 must be a symbol for 1, no matter what a represents. Similarly, a^{-n} must denote the reciprocal of a^n , since

$$a^m \times a^{-n} = a^{m-n} = a^0 = 1.$$

Again, a fractional exponent must, consistently with the above convention, indicate that a certain root of a power is to be taken. Thus the symbols

$$a^{\frac{1}{2}}, \sqrt{a}$$

ought to have the same meaning; for according to the conventional law of exponents,

EXPONENTIAL THEOREM

$$a^{\frac{1}{2}} a^{\frac{1}{3}} a^{\frac{1}{4}} = a^{\frac{1}{2} + \frac{1}{3} + \frac{1}{4}} = (a^{\frac{1}{2}})^{\frac{1}{3}} = a^{\frac{1}{6}}$$

The exponential notation was subsequently extended to symbols of operation. Thus if ϕ indicate any operation to be performed upon a quantity x , and $\phi(x)$ denotes the result of that operation, $\phi^2(x)$ would denote the result of operating, in a similar manner, upon the former result $\phi(x)$. For instance,

$$\phi(x) = 1 + 2x,$$

then

$$\phi^2(x) = \phi[\phi(x)] = 1 + 2(1 + 2x) = 3 + 4x.$$

Separating the symbols of operation and quantity, we might write as before,

$$\phi^{2+} = \phi^2 \phi,$$

and draw analogous conclusions. Thus, ϕ^0 would indicate an operation which, like the multiplication by unity, produces no change on the subject; that is to say, $\phi^0(x) = 1 \times x = x$. Again, ϕ^{-1} would indicate an operation whose effect is cancelled by the direct operation ϕ , and ϕ^3 would denote an operation which, repeated three times successively, yields the same result as the performance, twice successively, of the operation ϕ .

Exponential Equation. An equation which involves terms wherein the unknown quantity appears as an exponent or as a constituent of an exponent. The simplest form of exponential equation is $a^x = b$; one of its solutions is the *logarithm of b to the base a* , or, what is the same thing, the ratio of the logarithm of b to that of a , the bases being the same, but arbitrary. This is only one solution; the equation has innumerable other imaginary roots, and is consequently *transcendental*. A curve in whose equation the coordinates appear as exponents is, in like manner, called an *exponential curve*. The *logarithmic curve* may serve as an example.

Exponential Theorem. The expression of a number in ascending powers of its logarithm. It may be thus obtained:

$$\begin{aligned} \left(1 + \frac{1}{n}\right)^x &= 1 + x + \frac{x(x-1)}{1.2} \\ &+ \frac{x(x-1)(x-2)}{1.2.3} + \&c. \end{aligned}$$

by the binomial theorem. By putting $x=1$, and raising the result to the x^{th} power, this series, which is convergent for all values of $\frac{1}{n}$ less than unity, will manifestly be reproduced, and on supposing n to be infinitely great in the two identical series thus obtained, we have

$$\begin{aligned} 1 + x + \frac{x^2}{1.2} + \frac{x^3}{1.2.3} + \&c., \\ = \left[1 + 1 + \frac{1}{1.2} + \frac{1}{1.2.3} + \&c. \dots\right]^x = e^x. \end{aligned}$$

The number here represented by e has the value 2.7182818284 . . . , and is termed the

EXPORTS

base of the natural or Napierian system of logarithms. The above is the exponential theorem in its simplest form; it is convergent for all values of x . Putting $x \log_e a$ in place of x , and observing that $e^{x \log_e a} = a^x$, it becomes

$$a^x = 1 + (\log_e a)x + \frac{(\log_e a)^2}{1.2}x^2 + \&c. \dots,$$

which is the complete exponential theorem. If a^x be put in the form

$$[1 + (a-1)]^x,$$

and expanded by the binomial theorem, the coefficient of x , which by the above series is $\log_e a$, will be found to be

$$(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 \&c. \dots;$$

whence, putting successively $1+x$ and $1-x$ in place of a and deducting the results, is obtained the series,

$$\log_e \left(\frac{1+x}{1-x} \right) = 2 \left\{ x + \frac{x^3}{3} + \frac{x^5}{5} + \&c. \dots \right\},$$

by means of which natural logarithms may be calculated, and thence all others. [LOGARITHMS.]

Exports (Lat. *exporto, I carry out*). The commodities manufactured at home for the purpose of exchange against the productions of foreign countries, and shipped for that end, are popularly called by this name. These exports are valued at the time of shipment, and, as a rule, pay for the imports; the difference in value between the estimated price of imports and exports being, minus the charge of carriage, the profit of trade.

The following is the declared real value of British and Irish produce exported during the last sixteen years:—

	£		£
1849.	63,596,025.	1857.	122,066,107.
1850.	71,367,885.	1858.	116,608,756.
1851.	74,448,722.	1859.	130,411,529.
1852.	78,076,854.	1860.	135,891,227.
1853.	98,933,781.	1861.	125,102,814.
1854.	97,184,726.	1862.	123,992,264.
1855.	95,688,085.	1863.	146,489,768.
1856.	115,826,948.	1864.	160,436,000.

There is, however, another, and still more important sense, in which exports may be understood; that is, as including not only all manufactures and other goods shipped to foreign countries in payment of imports, but all the capital which seeks a more remunerative investment in foreign countries. This exportation of capital, though, comparatively speaking, scantily taken account of in investigating the trade of a country, produces most important effects on the foreign exchanges, and ultimately on prices at home; for when the amount of such investments or loans is added to the rest of the exports, it may induce an adverse state of the exchanges, necessitate the efflux of bullion, and, in order to arrest such an efflux, compel the levy of a high rate of discount, and, by forcing exportation at lower

EXTRACT OF LEAD

prices, diminish the rate of profit achieved by the manufacturer or producer.

Expression (Lat. *expressio*). In the Fine Arts, the representation of the various passions of the mind.

Exserted (Lat. *exsertus, thrust out*). In Botany, a term applied to tamens when longer than the corolla.

Exsicicator (Lat. *exsiccō, I dry up*). An apparatus for drying humid substances, consisting generally of a chamber through which a current of warm and dry air may be passed, and which may contain sulphuric acid, quicklime, or other substances which readily absorb aqueous vapour.

Extensor Muscles (Lat. *extendo, I stretch out*). As opposed to *flexor muscles*, those which extend any limb or part; the muscle in the fore-arm which extends the joints of the fingers, called the *extensor digitorum*, is an instance.

Extent. In Law, a writ of execution (sometimes called an *extendi facias*), directed to the sheriff, against the body, lands, and goods, or the lands only, of a debtor. Writs of extent were of two kinds—*extent in chief*, and *extent in aid*; to both of which the king was entitled by ancient prerogative, for the purpose of obtaining satisfaction of debts originally due to him, or assigned to the crown. The writ of *extent in chief* is a proceeding by the king for the recovery of his own debt, and in which he is the real plaintiff. The writ of *extent in aid* is also sued out at the instance and for the benefit of the crown against the debtor of a crown debtor; but in this proceeding the crown is the nominal plaintiff only, the party proceeding under the writ of *Extort* [which see]. Under this writ the lands, tenements, and possessions, as well as the person of the defendant, may be taken in execution; and if within seven days he do not liquidate the debt, a writ of *venditioni exponas* is issued to sell the same; the crown claiming a priority of satisfaction over every other creditor.

Extine. The external membrane of the pollen grain of plants. [EXTRINS.]

Extract or Extractive Matter (Lat. *extractus, part. of extraho, I draw out*). The term *extract* is applied in Pharmacy to the brown substance which remains after the evaporation of certain decoctions or infusions of vegetables; thus we have *extract of bark*, *extract of rhubarb*, and so on. These extracts are usually mixtures of various soluble matters, along with a certain portion of a peculiar vegetable principle of a brown colour, or which becomes so by exposure to air, and which is soluble in water and in alcohol, but scarcely soluble in ether. It combines with alumina, and is often the basis of brown dyes: it is this principle which chemists call *extractive*, and which is frequently closely allied to various forms of colouring matter.

Extract of Lead. A term applied to the impure subacetate of lead obtained by boiling litharge in vinegar. It was first used by a

surgeon of the name of Goulard, and hence called *Goulard's extract of lead*.

Extraction of Roots. In Arithmetic, the operation whose object is the discovery of the number which, when multiplied by itself, stated number of times, yields a given result. [EVOLUTION.] An interesting account of the progress made in the extraction of roots up to the year 1819, when Horner's admirable method was published in the *Phil. Trans.*, will be found in the *Companion to the British Almanac* for 1839.

Extradition (Lat. *ex*, and *trado*, I hand over). In International Law, the obligation of a state to surrender subjects of a foreign state charged with legal offences committed in such foreign state. This has been held by great jurists (Grotius among others) to follow from the comity of nations. Others deny this; and in practice, extradition is only made in cases where a convention to this effect subsists between two powers, as between England and France (February 1843), and the United States (August 9, 1842), enforced by stat. 6 & 7 Vict. c. 76, and 8 & 9 Vict. c. 120. (Phillimore's *International Law*, ch. xxi.) The rule of refusing the extradition of political refugees has been always maintained by Great Britain, and generally by civilised powers powerful enough to adhere to it. But Austria, Russia, and some of the German powers, have special treaties for this purpose.

Extrados (Fr.). The external outline, or curve, of an arch. Generally the term is used to denote the upper curve of the vousoirs, or stones, which immediately form the arch.

Extravagantes Constitutiones (Low Lat.). In the Canon Law, certain papal constitutions not included in the *Corpus Juris Canonici* are so called, and comprised in a separate volume. They are those of John XXII. and a few of his successors in the papacy.

Extravaganza (Ital.). In the Drama, pieces usually composed regardless of rules, and generally of the burlesque kind.

EXTRAVAGANZA. In Music, a kind of wild and incoherent composition.

Extravasation (Lat. *extra*, external to, and *vas*, a vessel). A term applied to fluids when out of their proper receptacles or vessels. Thus when blood is thrown out upon the brain, or into any cavities of the body, it is said to be extravasated.

Extreme (Lat. *extremus*). In Logic, has the same meaning with *term*, when used in reference to a proposition. The subject and predicate are the two extremes of a proposition, the copula being, as it were, placed between them. In speaking of a syllogism, the extremes are understood to mean the extremes or terms of the conclusion.

EXTREME. In Music, a word employed in describing those intervals in which the diatonic distances are increased or diminished by a chromatic semitone.

and Mean Ratio. A straight

line is said to be divided in extreme and mean ratio when the whole is to the greater part as the greater part to the less; or when the rectangle contained by the whole line and the smaller segment is equal to the square of the greater segment. Euclid shows how a line may be divided in this manner, in the eleventh proposition of his second book; and it is by means of this proposition that he constructs a regular decagon on a given straight line.

Extreme Unction (Lat. *unctio*, an anointing). One of the seven sacraments of the Romish church, founded on the passage in the Epistle of St. James, 'If any be sick among you, let him call upon the elders of the church, and let them pray over him, anointing him with oil in the name of the Lord' (v. 14). This ceremony is supposed to purify the soul of the dying person from any sins that he may have committed, and which have not been previously expiated by participation in the other means of grace.

Extremities. In Painting and Sculpture, the head, the hands, and the feet. In Zoology, the arms and legs, and analogous members in the lower animals.

extorse or Extrorsal. In Botany, a term used in describing the direction of bodies, to denote their being turned from the axis to which they appertain; thus anthers, whose line of dehiscence is towards the petals, are said to be *extorse*.

Extroversion. A term applied by surgical writers to those malformations of the body in which a part is, as it were, turned wrong side outwards. Such cases are congenital; thus cases are on record of *extroversion of the bladder*, in which there is a congenital defect of its anterior part, and of the corresponding portion of the parietes of the abdomen, so that the internal surface of the bladder projects and forms a tumour.

exuvise (Lat. *that which is cast off from the body*). This term was applied by the Roman naturalists and poets to the shed skin of the snake. It is extended in modern Zoology to the external layer of the integument of every animal, when it is periodically shed entire or in large portions. The films of mucus thrown off from the external surface of most zoophytes and molluscs may be regarded as exuvise; also those portions of the shell which are deserted and partitioned off by a new-formed plate, as in the *Spondylus varius*, and chambered univalve shells; but the exuvial layers are retained by adhesion to the last secreted portion of the shell. In insects the whole integument is shed generally several times in succession, the last *ecdysis* taking place in the transition from the pupa to the imago state. In the *Crustacea* the exuvial shell is commonly cast annually; the cephalothorax or carapace cracks longitudinally down the back, and the limbs are withdrawn after successive painful efforts; the lining membrane of the stomach is at the same time shed.

Fishes seem to cast off exuvial layers of mucus only; but in most reptiles the epidermis is

EXUVIÆ

periodically moulted, either entire or in large coherent masses. In some species the moulting could only have been detected by careful watching, as the main evidence, the cast skin, is made away with the moment the operation is ended. Mr. Bell thus describes the *ecdysis* of the common toad: 'On watching carefully, I one day observed a large toad, the skin of which was particularly dry and dull in its colours, with a bright streak down the mesial line of the back; and on examining further, I discovered a corresponding line along the belly. This proved to arise from an entire slit in the old cuticle, which exposed to view the new and brighter skin underneath. Finding therefore what was about to happen, I watched the whole detail of this curious process. I soon observed that the two halves of the skin thus completely divided continued to recede further and further from the centre, and become folded and rugose; and after a short space, by means of the continued twitching of the animal's body, it was brought down in folds on the sides; the hinder leg, first on one side and then on the other, was brought forward under the arm, which was pressed down upon it; and on the hinder limb being withdrawn, its cuticle was left inverted under the arm, and that of the anterior extremity was now loosened, and at length drawn off by the assistance of the mouth.' The whole cuticle was thus detached, and was now pushed by the two hands into the mouth in a little ball, and swallowed at a single gulp.' The common snake (*Colester Natrix*) when in confinement moults as follows: The formation of the new cuticle produces a detachment of the old from the subjacent living parts, and the latter then loses part of its transparency and smoothness. As the cuticle is continued over the cornea, the sight of the serpent is dimmed; its motions are also in some degree cramped, and it endeavours to free itself of its encumbrance by rubbing the sides of its mouth against any rough and hard resisting substance. The old cuticle is thereby detached from the circumference of the mouth, and is turned back over the head; and the impediment to vision being thus removed, the snake proceeds with more vigour and rapidity to detach and turn back the cuticle, by repeating the same actions as those with which it commenced the operation; and at length it literally creeps out of its skin, which is left inverted, and more or less entire, according to the degree of the animal's health and vigour at the time of the operation. The rattlesnake is described as actually inverting and drawing off its own skin. After having rubbed back the cuticle from the head, it throws the posterior part of the body in numerous coils around the anterior; one coil is placed in front of the detached part of the integument; and compressing the body strongly, it pushes forward the head and neck, gradually unrolling the coils behind, and stripping off the skin, as it advances forwards. In the warm-

the periodically moulted feathers of birds, and hairs of various species of, may be regarded as exuvial deposits;

EYE AGATE

as also the small scales of the scarf-skin which are incessantly cast off in man.

Oculus (A. Sax. eage, Ger. auge, Lat. oculus). In describing the structure of the organ of vision, anatomists generally refer to external and internal parts: the former include the eyebrows, or *super-cilia*; the eyelashes, or *cilia*; and the eyelids, or *palpebrae*. The cartilaginous edge of the eyelids is called the *tarsus*, in which, as in the inner surface of the eyelids, are small glands which secrete a lubricating serous fluid, called, after their discoverer, the glands of Meibomius. Near the external corner or *canthus* of the eye, and in a depression of the frontal bone, are the lachrymal glands (*glandula lachrymalis*), which secrete tears; their ducts open on the inner surface of the upper eyelid. The little projection at the inner angle of the eye is called the *lachrymal caruncle*. There are also two small orifices observable at the inner angle, one in the upper and one in the lower eyelid, which are called the *puncta lachrymalia*; they convey the tears by means of two small tubes to the *lachrymal sac*, whence they pass by the *nasal duct*, which opens under the inferior spongy bone, into the nose. The conjunctive membrane of the eye, called also *tunica albuginea*, or white of the eye, is a membrane which lines the inner eyelids and the fore part of the globe of the eye. The internal parts of the eye are: the *sclerotic membrane*, which is the hard outer case of the globe; the *choroid membrane*, which is the interior coat of the sclerotic, beginning around the optic nerve, and proceeding to the margin of the transparent cornea, where it deflects inwardly, forming the *iris*, the posterior surface of which is called the *uvula*, and its central opening the *pupil*, which is muscular, admitting of dilatations and contractions so as to modify the quantity of light admitted into the inner chambers of the eye. The *crystalline lens* is a pellucid body included in a delicate capsule, and lodged in a concave depression of the front of the *vitreous humour*, which is a transparent and pellucid pulpy texture, filling the ball of the eye behind the lens, and covered externally by the *hyaloid* or *arachnoid* membrane. The optic nerve enters the back of the eyeball by a perforation in the sclerotic and choroid coats, and is spread upon the posterior and inner surface of the latter, forming a pulpy film or nervous matter called the *retina*. The eye is moved by six appropriate muscles. In the annexed cut, representing a section of the ball of the eye, *a* is the sclerotic membrane or coat, *b* the iris, *c* the retina, *d* the optic nerve, *e* the vitreous humour, and *f* the crystalline lens. [Orrice; Vision.]

Oculus, *Agate*, The name given to those kinds of circle agate, the central parts of which are of deeper tints than the rest of the mass.

EYE OF A DOME

The term *eye agate* is also applied to stalactitic carbonate of lime, when sections made at right angles to the axis display a darker coloured spot in the centre, presenting a fanciful resemblance to the pupil of the eye.

Eye of a Dome. In Architecture, the circular aperture in the summit through which light is admitted.

Eye Stone. A small calcareous stone found in the shells of some mollusca, and formerly used for removing substances from between the lid and the ball of the eye.

Eye of a Volute. In Architecture, the circle in its centre.

Eye-bolt. On Shipboard, a pointed iron bar with a hole at the thick end. It is intended to be driven into one of the timbers, and then to have a rope passed through the hole.

Eye-piece. An eye-piece, or *power* as it is sometimes called, is the lens or combination of lenses used in microscopes or telescopes to examine the aerial image formed at the focus of the object-glass. The ordinary eye-piece is a combination, and may be either *positive* or *negative*. The former consists of two plano-convex lenses, with their convex sides towards each other; and is used for micrometers. The negative or Huygenian consists of the same lenses with the convex sides turned away from the eye. Besides these there are in use, for observations of the sun, a *diagonal eye-piece*, in which a very small percentage of the sun's light and heat is reflected from the first sur-

FABLE

face of a prism, the rest being transmitted; and *Dawson's solar eye-piece*, in which the light is reduced by observing only an extremely minute portion of the solar surface. Steinhil and Kellner have also contrived *eye-pieces*; they, however, are not in such general use. The eye-piece of opera-glasses consists of a combination of biconcave lenses—an arrangement which is almost out of date as applied to telescopes, although occasionally it may be used with advantage.

All these eye-pieces except the last mentioned invert. The *terrestrial* or *erecting eye-piece* is a combination of four lenses, used for terrestrial telescopes.

In eye-pieces, as in object-glasses, the optician has to get rid of spherical and chromatic aberrations: it is also a *sine qua non* that the field of view shall be flat. Those who wish for more information on this subject should refer to exhaustive memoirs by Mr. Airy (*Cambridge Phil. Trans.* vols. ii. and iii.), or a paper by Biot (*Mémoires de l'Institut*, 1843).

Eye-teeth. The two upper cuspidati are so called in consequence of the length and direction of their fangs, which extend upwards nearly to the orbit of the eye.

Eyebright. [EUPHRASIA.]

Eyre. In old English Law, signified the court of justices itinerant. The term is in all probability derived from the Lat. *iter, journey*; as Bracton styles the justices who presided in these courts *justiciarii itinerantes*.

F

F. The sixth letter of the English and Latin alphabets; a labiodental aspirate, bearing the same relation to the other labiodental aspirate, V, which the letters called *tenuis*, *p*, *k*, *t*, bear to the *media*, *b*, *g*, *d*. It corresponds with the DIGAMMA [which see] of the Æolian dialect, to which it is closely related both in form and power; and is susceptible of a few interchanges, chiefly in the Spanish and Latin languages.

F. In Music, a note of the scale, corresponding with the *fa* of the French.

Fa. In Music, one of the syllables invented by Guido Aretino to mark the fourth sound of the modern scale of music; rising thus: *ut, re, mi, fa*. It is now used by the French and Italians to designate our note F.

Faba (Lat. *a bean*). A genus of Leguminous plants, comprising the common annual Bean, *F. vulgaris*, a vegetable supposed to have been originally derived from the shores of the Caspian. As an esculent, the parts eaten are the young seeds, which are very nutritious. Beans are also cultivated as a farm crop, the varieties

being different from those grown in gardens. They are used in a bruised state as food for horses, and ground into meal for fattening pigs, &c. *Kidney beans* are the produce of a species of *Phaseolus*.

Fabaceæ. [LEGUMINOSÆ.]

Fable (Lat. *fabula*). In Literature, a term applied originally to every fictitious tale; but confined in modern usage to a class of tales, either in prose or verse, which inculcate a moral precept through the medium of a short fictitious story. In the very ancient Indian Fables of Pilpay, the Arabian of Lockman, and the Greek of Æsop, the fictitious personages introduced are chiefly animals, endued for the purpose of the story with human faculties and language; and hence modern fabulists have generally introduced similar agents in the greater number of their fables. In this sense, the fable is synonymous with *apologue*, and belongs to the class allegory. Fables are either in prose or verse; but if the latter, they will not bear with propriety a highly poetical or ornamental character. Herder has divided

FABLIAUX

fables, according to the character of their meaning, into three classes: 1. Theoretic, intended to form or exercise the understanding; 2. Moral, which contain rules for the regulation of the will; 3. Fables of fate or destiny, in which the narrative contains no maxim of self-conduct, as it merely represents a series of contingencies brought on by necessary connection. But it may be doubtful whether every fable, in the sense in which the name is generally used, does not belong properly to the second class; the instances cited by Herder as appertaining to the first and third were certainly intended by the inventors to bear a moral meaning.

Fabliaux (Fr.). In French literature, the metrical tales of the Trouvères or early poets of the Langue d'Oïl, or dialect of the north of France; composed, for the most part, in the twelfth and thirteenth centuries.

Fac. In Printing. The name *fac* (facsimile) was given by the early printers to the large ornamental letter used at the commencement of a division of a book.

The first books were printed in imitation of, and sold as, MSS.; and the printers left a blank space at the beginning of books, chapters, &c., for an illuminator to fill in the proper letters, with appropriate ornaments in gold, silver, and colours. When printing became no longer a secret, and the deception could not be continued, ornamental letters of a large size were introduced, and printed with two colours, generally red and blue, the letter being of one colour, and the flourishes (extending the whole length of the page) in the other, so as to have the appearance of being done with a pen. Then succeeded various grotesque figures, to resemble letters, and afterwards small capital letters, with ornaments round them, forming a square design. Subsequently the block was pierced so that any letter could be introduced, and the ornamental part used for any initial; and the next plan was for the type-founders to cast the letters in type-metal, and pierce them for general use. Lastly, we have what is called a *two-line letter*, a large type extending to the depth of two or more lines, the modern representative of the beautiful coloured initials of the illuminati.

Fac-simile (Lat. *make-like*). This term, expressed in French by the words *fais-semblable*, signifies an exact and faithful copy of any writing, engraving, or other work of art.

Façade (Fr.). In Architecture, the face, or front, of any building towards a street, court, garden, or other place, is called the *façade*; but the term is more commonly applied to the principal elevation of the building to which it is desired to direct attention.

Face (Lat. *facies*). In Fortification, one of the sides forming the salient angle of a ravelin or bastion.

Facm. In Solid Geometry, any one of the planes which form the surface of a polyhedron.

Facet (Fr. *facette*). A lapidary's term for the small plane surfaces cut on precious stones

FACTOR

to reflect the light, and so to increase their lustre.

Facial Angle. [ANGLE, FACIAL.]

Facients (Lat. *faciens*, part. of *facio*, *I make*). In modern Algebra, the variables of a quantic as distinguished from the coefficients. (Cayley 'On Quantics,' *Phil. Trans.* 1854.)

Facies Hippocratica (Lat.). The peculiar expression of countenance which indicates the approach of death; it has been accurately described by Hippocrates, whence the above common medical term.

Facing. In Architecture, this term is generally employed to mean the better description of material which serves to mask an inferior one, as when stone facing is used upon brick-work, &c.

Faction (Lat. *factio*). By the ancient Romans this appellation was given to the different troops or companies of combatants in the games of the circus. Of these factions there were four—the green, blue, red, and white; to which two others were said to have been added by the emperor Domitian—the purple and the yellow. In the time of Justinian 40,000 persons were killed in a contest between two of these factions; and they were at last suppressed by universal consent. The term *faction* is applied also, in a more general sense, to any party in a state which attempts without adequate motives to disturb the public repose, or to assail the measures of government with uncompromising opposition. In the ancient Greek republics, faction was carried to an extent unparalleled in modern times. The middle ages were distinguished chiefly by two factions, the Guelphs and Ghibelins, who long kept Italy in a state of alarm. In England, the term *faction* was long bandied about between the three great parties of the country, the Whigs, Tories, and Radicals, being applied indiscriminately by the adherents of one party to those of the other. [PART.]

Factor (Lat.). In Arithmetic and Algebra, the name given to each of the quantities which we multiply into one another in order to form (*facere*) a product. The factors of a number are its several *divisors* or *measures*.

FACTOR. In Mercantile Law, a mercantile agent, who is intrusted with the possession of the property which he is commissioned to dispose of. Under the law which obtained previously to the passing of the Act 6 Geo. IV. c. 94, it was held that a factor, as such, had authority to sell only, and not to pledge, the goods of his principal; and, consequently, that a party who had made a *bond fide* advance to the factor on the credit of the goods was liable to restore them to the principal without his being bound to repay the advance. By that statute it is enacted, that any person intrusted, for the purpose of consignment or sale, with goods, &c., and in whose name such shall have been shipped, shall be deemed the true owner, so far as to entitle the consignee to a lien thereon in respect of any money or negotiable security advanced by such

FACTOR, INTEGRATING

consignee for the use of the person in whose name such goods, &c. shall have been shipped: provided the consignee has no notice, by bill of lading or otherwise, that such party is not the true owner. Various other provisions are added by the same Act, to the effect that persons in possession of bills of lading shall be deemed owners, so far as to make valid contracts; that no person can acquire a security upon goods in the hands of an agent for an antecedent debt beyond the amount of the agent's interest in the goods; that persons may contract with known agents in the ordinary course of business, or out of that course, if within the agent's authority; that persons may accept and take goods in pledge from known agents; and a right is preserved to the true owner to follow his goods, while in the hands of his agent or the agent's assignee, in case of the bankruptcy of such agent or assignee. A factor has a general lien on goods consigned to him, not only for incidental charges, but as an item of mutual account for the balance due to him, as long as he remains in possession.

* In Scotland, the term *factor* is used synonymously with *steward* in England; it is also the title of an officer, who may be appointed by parties to act as *attorney* in English law, or by the courts (judicial factor) to take charge of the estate of a minor or absent person, &c.; now regulated by 12 & 13 Vict. c. 51.

Factor, Integrating. [INTEGRATING FACTOR.]

Factorials. A name given to the factors of a continued product when the former are derivable from one and the same function $F(x)$ by successively imparting a constant increment or decrement h to the independent variable. Thus the product

$F(x) \cdot F(x+h) \cdot F(x+2h) \dots F(x+(n-1)h)$

is called a *factorial term*, and its several factors take the name of *factorials*. The symbols $x^{(n)}$ and $x^{(-n)}$ are frequently employed to denote, respectively, the factorial terms

$$x(x-1) \dots (x-m+1),$$

and

$$\frac{1}{x(x+1) \dots (x+m-1)}.$$

Factory (Lat. *factor*, a maker). The earliest usage of this term was to signify a *dépôt* for goods. In this sense the settlements of the East India Company were called *factories*. Gradually, however, the word has been limited to establishments in which certain commodities are manufactured, as cotton and woollen stuffs, and hardware generally.

Reports of the wretched condition of work-people in factories and collieries, and evidence collected before parliamentary committees, led to the framing of factory Acts for the supervision of these establishments. The legislation was resisted partly on the ground of its being a mischievous interference between employer and employed, partly because it was one-sided in its operation. The last objection was unquestionably the most important. In

FACULTY

general, factory Acts involve the nomination of an inspector, to whom a district is assigned, and secure that persons of tender years shall not be employed at all, and that others older, but still below a certain age, shall only be employed at half time, provision being made for the education of children. In some cases provisions are made against the employment of women.

In practice it has been found that these limitations have been politic, however little we may believe that policy led to the enactment of the factory laws. Experience has shown that a limitation of the hours of labour, especially in the case of young persons, is followed by greater effectiveness in the labour afforded; and, on the whole, the manufacturer has been rather benefited than injured by the restrictions. But what applies to one class of employment, applies to all equally; and if supervision and limitation are desirable in the case of juvenile and female labour in certain establishments, they must be so in others, whether in town or country. There cannot be the smallest reason why the labour of children should be prohibited in large and well-ventilated factories, and permitted in agriculture—why women should be protected in a colliery, and worked to death in a sloopshop.

The chief authority on factory regulations and similar sanitary measures is Mr. Edwin Chadwick, whose writings on the subject may be examined with advantage. [TAVUK SYSTEM.]

Faculee (Lat. dim. of *fax*, a torch). In Astronomy, those portions of the sun's disc which appear brighter than the rest of his surface. Recent investigations, and an examination of the Kew sun pictures, render it probable that these are the highest portions of the sun's cloudy photosphere. [SUN.]

Faculty (Lat. *facultas*). In Ecclesiastical Law, a license or authority to do or enjoy a certain thing, as the right to a pew, or monument, or particular mode of burial. The grant of faculties is a jurisdiction belonging to the archbishop or bishop. [ECCLESIASTICAL COURTS.]

FACULTY. In the Universities. In the origin of the university of Paris (which is considered as the model of all European institutions in the middle ages) the seven liberal arts (grammar, logic, rhetoric, arithmetic, geometry, astronomy, and music) seem to have been the subjects of academic instruction. These constituted what was afterwards designated the Faculty of Arts. Three other faculties—those of divinity, law, and medicine—were subsequently added. In all these, lectures were given, and degrees conferred by the university. The four faculties were transplanted to Oxford and Cambridge, where they are still retained; although, in point of fact, the faculty of arts is the only one in which substantial instruction is communicated in the academical course. By an anomaly of ancient date, the English universities also give degrees in what is not properly a faculty, but only a branch of one of the faculties, viz. music. On the Continent, the faculty of arts is

FACULTY, DEAN OF

synonymous with that of philosophy. In England, that of divinity is not wholly distinct from, but superior to, that of arts; degrees in the latter being preliminary qualifications for those in the former.

Faculty, Dean of. In Scotland, the elective president of the faculty of advocates, answering to barristers in England.

Fæces (Lat.). The excrements; usually confined, in Physiology, to the solid matter evacuated from the alimentary canal. According to the analysis of Berzelius, human fæces of consistence sufficient to form a coherent mass are composed of:—

Water	.	.	.	75.3
Matters soluble in water	{	Bile	0.9	5.7
		Albumen	0.9	
		Peculiar extractive	2.7	
		Salts	1.2	
Insoluble residue of the food				7.0
Insoluble matters which are added in the intestinal canal—mucus, biliary resin, fat, and a peculiar animal matter				14.0
				102.0

The influence of various foods upon the composition of excrement has been experimented upon by Dr. Marcet, *Philosophical Transactions*, 1861. [EXCREMENT.]

Fæcula or **Fecula** (Lat. dim. of *fax*, a sediment). When certain vegetable products are bruised and mixed with water, the pulverulent matter which subsides is called the *fæcula* or *fæces*. [STARCH.]

Fænix. [ŒDIPUS; PERSEPHONE.]

Fagging. [PUBLIC SCHOOLS.]

Fagine. A crystalline alkaloid found in beech-nut (*Fagus sylvatica*).

Fagopyrum (Gr. *φῦρος*, Lat. *fagus*, and *rupis*, wheat). The genus of the Buckwheat, *F. esculentum*, sometimes known as *Polygonum Fagopyrum*. It is a native of Central Asia, but has been so long cultivated as to have become naturalised in many parts of Europe. In this country, it is chiefly grown for the purpose of affording food for pheasants.

Fagus (Lat.). The Beech-tree of our woods, *F. sylvatica*, is the principal member of this genus of *Corylaceæ*. It is a native of Europe and Asia, and forms a large handsome tree, especially when growing on chalky hills. Its timber, though not of the first quality, is useful for many purposes, and it is also one of the most useful kinds of wood for fuel. The three-cornered nuts are edible, and much sought after by swine, and an oil is expressed from them. In gardens, the Purple and Copper leaved varieties are trees of great beauty.

'*Phægos*, in Greek, means oak, never beech: in Latin and Gothic, *fagus* and *bêka* signify beech, and beech only.' In the same way, the Latin *quercus*, which signifies only oak, represents the Teutonic word *fir*. These singular changes in the meaning of the same words are probably to be explained by the change of vegetation which took place since the arrival

FAIRIES

of the Greek, Latin, and German races in their European homes. Similar changes, going on in words at the present day, explain the fact that the Greek *phægos* retained its old meaning, while the Italian and Teutonic Aryans applied the word to the new beechen forests which were springing up around them. (Max Müller, *Lectures on Language*, second series.)

Fahlers (Ger.). A mineralogical synonym of Grey Copper Ore.

Fahlunite. A mineral, from *Fahlun*, in Sweden. It is a hydrated silicate of alumina.

Falence (from Faenza, the original place of manufacture). In the Fine Arts, pottery, consisting of a common earthenware ground, covered with a glaze, and enamelled with painted designs. It is also called *Raphael ware*, because Raphael was thought in his early days to have been engaged on this department of the art: but this is a vulgar error; the Raphael who was employed in painting pottery was a Raffaello Ciarla of Urbino, who lived in the middle of the sixteenth century. Although it is true that many of Raphael's designs have been painted on pottery, none were so painted during his lifetime.

Fainting. [SYNCOPE.]

Faints. The impure and weak spirit constituting the last runnings of the still, used in the manufacture of alcohol.

Fair (Fr. *foire*). A meeting held at stated times of the year in particular places, for the purposes of traffic, to which merchants resort with their wares. Fairs, in Christian countries, were usually held on particular festivals; and are so still in England, unless where they have been fixed to particular days in the month by later grants of privileges. By the English law, the king's authority only is supposed to confer the privilege of holding a fair, with the court of pie-powder to determine disputes arising there. Fairs are considered free, unless toll is due to the owners by special grant, or by custom, which supposes such grant.

Fairies (Fr. *fee*, a *fairy*; *féerie*, witchery; Ital. *fata*, a *fairy* or *witch*, from Lat. *fatum*, fate). Imaginary beings, in the traditional mythology of the nations of Western Europe, and especially in these islands. The resemblance of their English name to that of the *Peris* of the Persians (pronounced *Feri* by the Arabians) seems to be merely accidental. The British fairies, although they have something in common with the *Dwergas* or *Gnomes* of the Scandinavian mythology, are not identical with them; they are in fact peculiar to people of Celtic race, and the notions respecting them prevalent among the Celtic population in Scotland, Wales, and Ireland tally to a remarkable degree. The popular belief, however, was nowhere invested with so poetical a character as in the Lowlands of Scotland, where it forms a main ingredient in the beautiful ballad poetry of the district. The fairies of the Scottish and English mythology are diminutive beings, who render themselves occasionally visible to men, especially in exposed places, on the sides

FAIRY RINGS

of hills, or in the glades of forests. They have also dealings with men, but of an uncertain and unreal character. Their presents, though sometimes valuable, are generally accompanied with some condition or peculiarity which renders them mischievous: more often they turn into dirt or ashes in the hands of those to whom they have been given. Mortals have been occasionally transported into Fairy-land, as in the legend of Thomas the Rhymer. The popular belief in fairies has been made the subject of poetical amplification in the hands of so many of our greatest writers, from Shakspeare to Scott, that it is not easy to disentangle embellishments from the original notions on which they are founded. The Fata of the Italians, who figures in their romantic epics, and from whom the French have made the *Fées* of their fairy tales, is a female magician, sometimes benevolent and sometimes malevolent, having a supernatural character, and gifted with the spirit of prophecy. Such is the Fata Morgana, to whom the celebrated optical delusion occasionally produced in the straits of Messina was formerly attributed by popular belief.

Fairy Rings. The green circles or parts of circles sometimes seen in pastures. They are produced by certain Fungi, chiefly species of *Agaricus*, in this way: A patch of spawn spreads in every direction, and produces at its edge a crop of its particular fungus; the spawn exhausts the inner portion of soil, so that the spawn there dies, but the crop of fungi meanwhile perishes, and supplies a rich manure to the grass, which in consequence becomes of a vivid green. The spawn progresses outwards, and the process of exhaustion and renewal goes on, so that the ring increases in diameter year after year, till it is sometimes several yards across. *Agaricus oreades*, *gambosus*, and *arvensis* are some of the principal species which give rise to these mysterious-looking rings. The reader is referred to a paper on this subject, by Dr. Wollaston, in the *Philosophical Transactions* for 1807, p. 133.

Faith (Lat. *fides*). In Theology. It is observable that the writers of the New Testament employ one and the same word for faith and belief. In most modern languages, the use of two different terms has, perhaps, strengthened the feeling of a difference between the conviction of the heart and that of the understanding: the German, like the Greek, has one only. Faith, in the language of the Epistle to the Hebrews, is 'the substance of things hoped for, the evidence of things not seen.' Perhaps these expressions might be more accurately rendered 'confidence' in things hoped for (compare 2 Cor. ix. 4; xi. 17), 'conviction' of things not seen (Heb. xi. 1). Through this faith, it is declared that men receive as true things delivered to them on divine authority, to which neither their senses nor their uninstructed reason bear testimony, and endure sufferings and do great actions for God's sake, while without it 'it is impossible to please Him.' Such faith 'was imputed' to Abraham 'for

FALCO

righteousness' (Rom. iv. 21); and thus 'being justified by faith, we have peace with God through Jesus Christ.' (Rom. v. 1.) It is evident from these as well as many other passages in the Apostolic Epistles, that this justification is spoken of as attained only by that faith which obeys the command as well as relies on the promise of God; termed by theologians *efficacious* or *saving* faith.

Fake of a Cable or Rope. In Nautical language, this term is applied to any one of the circles formed by a cable or rope, as it lies in a coil.

Fakir. An Arabic word signifying *poor*; applied in some Eastern countries to a sect of enthusiasts, who retire from the world and devote themselves to religious observances. They are chiefly remarkable for their assiduity in 'mortifying the flesh,' considering no infliction of the body as too severe, provided they can inspire the observer with reverence towards them. There are, however, some classes of Fakirs distinguished for good sense, learning, and piety.

Falcate (Lat. *falcatus*, *sickle-shaped*). In Botany and Zoology, when any part is curved with an acute apex.

Falcated (Lat. *falx*). The moon is said to be *falcated* when her illuminated part appears in the form of a crescent or sickle, which happens when she is in the first and fourth quarters.

Falchion (Fr. *faucon*, Lat. *falx*). A sword in use in the thirteenth century, with a broad blade, widening towards the point, the edge convex.

Falciform Process of the Brain (Lat. *falx*). A process of the *dura mater*, which arises from the *crista galli* and terminates in the *tentorium*, separating the hemispheres of the brain.

Falco (Lat. *a falcon*). The name of a Linnæan genus of Accipitrine Diurnal birds, characterised by a beak crooked, and covered with a cere at the base; head closely invested with feathers. To the short Linnæan phrase descriptive of this group of birds of prey may be added, that the supraciliary arch projects above the eye, giving a bold and threatening physiognomy to these rapacious birds, the majority of which subsist on living prey. The first plumage differs from that of maturity, which is not acquired before the third or fourth year. The female is generally one-third larger than the male. The Linnæan genus is now subdivided into the subgenera *Falco*, Bechstein; *Hierofalco*, Cuv.; *Aquila*, Brisson; *Haliastur*, Savigny; *Pandion*, Sav.; *Circæus*, Vieillot; *Harpyia*, Cuv.; *Morphnus*, Cuv.; *Astur*, Bechstein; *Nisus*, Cuv.; *Milvus*, Bechstein; *Pernis*, Cuv.; *Buteo*, Bechstein; *Circus*, Bech.; *Gypogeryan*, Illig. Of these subgenera, the first two form what are termed the *noble* birds of prey, and they are the most courageous in proportion to their bulk. This quality is associated with a powerful form of the beak, of which the cere commences from the base, and which is armed with a strong tooth on each side near

FALCONINES

the apex. Their wings are strong, long, and pointed, the second quill-feather being the longest. It is from this division of falcons that the birds are selected for the sport of falconry. In the ignoble division of the birds of prey, the longest quill-feather of the wing is almost always the fourth, and the first is very short, which gives the wing an appearance of having the extremity obliquely truncated. The bill is not armed with lateral tooth-like processes.

Falconines, Falconinæ (Lat. *falco*). subfamily of Accipitrine birds, having the genus *Falco* proper as the type; and characterised by a beak short, hooked from its base, and toothed near the apex; wings long, second quill shortest. It includes the genera *Ferax* and *Falco*. The term *Falconidae* is used by some ornithologists in a sense as extended as *DRUPÆ* [which see].

Falconry. The origin of this celebrated sport has given occasion to much controversy. It has been said that it was unknown to the Greeks; it is, however, described by Ctesias and Aristotle as practised in their time in India and Thrace. Martial and Apuleius present us with plain indications of the knowledge of this pastime among the Romans. In modern Europe, it appears to have been practised earliest, or at least with most ardour, in Germany: the title of the emperor, Henry the Fowler (A.D. 920), is said to be derived from an anecdote respecting his fondness for it. In the twelfth century, it was the favourite sport of nobles and knights throughout Europe; and in the thirteenth its rules were reduced into a system by the emperor Frederick II., and by Demetrius, physician to the Greek emperor Palæologus. In that court the grand falconer was an officer of distinction, and the title was borrowed from it by the Western sovereigns. According to the opinion of Strutt, the sport was not known so early in England as on the Continent; yet there are traces of it as early as the eighth century. From the commencement of the seventeenth, we may date its gradual decline. James I., devoted to hunting, was no admirer of falconry, which up to his time had been the favourite royal sport. But its final abandonment, except as the fancy of a few individuals, was owing to the gradual improvement in firearms presenting far easier methods of obtaining game. Among the many curious works which exist on this subject, once so universally interesting, may be mentioned the treatise *De la Fauconnerie* of Charles d'Espèron, Paris 1606; the celebrated *Book of St. Albans*, by the Prioress Juliana Berners, 1486; Latham *On Falconry*, 1658; Ray's *Idea of Falconry*, published with Willoughby's *Ornithology*. The emperor Frederick II. did not disdain to give the world the results of his experience in the art, in a treatise published in 1596 from his MS., under the title *Reliqua Librorum Frederici II. Imp. de Arte Venandi cum Avibus*.

Falculite (Lat. *falcula*, dim. of *faix*, a sickle). In Zoology, a claw is so called when it is compressed, elongate, curved, and sharp-pointed.

FALLOW

Fall. The Sea term for that rope of any pulley or system of pulleys to which the pressure or moving power is applied. To *fall aboard* signifies to run foul of another vessel.

FALL. A Scotch measure of length and surface, the former being equal to six Scots ells, or 6·1764 English yards; and the latter being equal to 36 square ells.

Fallacy (Lat. *fallacia*, from *fallō*, I deceive). In Logic and Rhetoric, any argument, or apparent argument, which professes to be decisive of the matter at issue, while in reality it is not. Fallacies have been divided into those in *dictione*, in the words; and *extra dictione*, in the matter. The latter of these it is not the province of logic to discover and refute; they being, strictly, instances in which the conclusion follows from the premisses, and which therefore depend on the unsoundness of these premisses themselves, which can only be detected by a knowledge of the subject-matter of the argument. Logical fallacies, or fallacies in dictione, are those in which the conclusion appears to follow, but in reality does not, from the premisses; and which, consequently, can be detected by one unlearned in the subject-matter of the argument, but acquainted with the rules of logic. These are subdivided, however, into fallacies purely logical, i.e. vicious syllogisms [SYLLOGISM; PARALOGISM], and fallacies semi-logical, those namely which arise from the employment of a middle term in argument [SYLLOGISM; PROPOSITION; MIDDLE TERM] ambiguous in sense. In rhetoric, a common set of artifices, by which the mind of the reader or hearer is diverted from the question at issue and fixed on some collateral topic, are termed *fallacies*; as, where the character of the proposer of a measure is discussed as a reason for or against the measure itself, &c. &c.

Falling Home. The term applied to the timbers or upper parts of the sides of a ship when they curve inwards. The old ships fell home, or tumbled in (as it is also called), much more than the modern ones, which approach more nearly to being *wall-sided*.

Falling Sickness. [EPILEPSY.]

Falling Stars. [SHOOTING STARS.]

Fallopian Tube. The name given to a canal or tube, discovered by Fallopius, arising at each side of the fundus of the uterus, and terminating in the ovarium.

Fallow (possibly connected with Scotch, *fail*, a sod or turf, Swed. *vall*, sward; Wedgwood). In Agriculture, lands are said to be under fallow when under cultivation whether with or without a crop. A naked fallow is one in which the soil remains a whole year without any crop whatever; and a turnip or green crop fallow is one in which the lands, after being without a crop from harvest till the beginning of the following summer, and being properly laboured during that period, are sown with turnips or other similar crops in rows, and the ground cultivated in the intervals. Fallowing practised by the Romans on all soils, and

FALLOW DEER

has been continued through the dark ages, in all the cultivated parts of Europe, so as to have become, till lately, a general habit in the treatment of arable lands. The practice of taking two corn crops, and then allowing the land to rest or lie fallow, was till the commencement of the present century prevalent throughout Europe; and it is still a very common practice in most parts of the Continent. It appears to have been first broken through by the Flemings about the end of the sixteenth century and subsequently in Britain, with the culture of turnips, above a century and a half later. Bare fallows, under the most improved systems of agriculture, are no longer had recourse to in the case of free or easily worked soils, where turnip fallows are made, or drill crops of legumes are substituted; but in very strong clays they are still found necessary, and this will probably continue to be the case till by thorough drainage, and perhaps steam culture, the strong clays become friable and fit for the drill husbandry, like the sandy loams and other free soils.

Fallow Deer. The *Cervus Dama* of Linnæus. It has nearly superseded the old English Red Deer in the British parks. Its introduction from the south of Europe was effected during historical times; but a fossil species, apparently indistinguishable from the recent one, existed in the post-pliocene age. [DEER.]

False Cadences. In Music, one wherein the bass rises a tone or semitone, instead of rising a fourth or falling a fifth.

False Keel. The timber added below the main keel, to serve as a defence in case of grounding; also, by deepening the vertical plane, to enable the ship to take a better hold on the water, and therefore to carry sail with greater ease.

False Pretences, Obtaining Property by. In Law, is distinguished from *larceny* as being perpetrated through the medium of mere fraud. At common law it is a misdemeanour; but for the purposes of justice the distinction between the two offences is now rendered by statute practically unimportant.

Falsetto (Ital.). In Music, that part of a person's voice which lies above its natural compass, and is produced to various extents in different subjects, male as well as female. It rarely extends more than four or five notes above the natural voice, and is produced by diminishing the aperture of the throat.

Faluns. In Geology, a name given to the low cliffs on the Loire and other French rivers, and thence applied as a geological name owing to the occurrence in these cliffs of large and interesting series of fossils of a definite geological period. The Faluns of Touraine are typical of the *miocene* or middle tertiary period. The name *falun* seems to belong especially to certain banks of shelly gravel, such as in Suffolk are called *crag*, extending at intervals from Dinan in Brittany to the Loire. They are very rich in fossil shells.

Fama (Lat.). The Latin personification of Rumour. (Virg. *Æn.* iv. 174.) In Homer

FAMILY COUNCIL

it was represented under the name *Ossa*. (Od. xiv. 413.)

Familia (Lat.). In Roman Antiquities, a house or family, being a subdivision of *gens* or clan. [GENA.] Its members were distinguished by using the same *cognomen*, the family name. The word was also employed to denote all that was subjected to the will of one man, whether free persons or slaves, or material property, and was sometimes limited to the slaves of a household.

Familiar or Familiar Spirit. Familiar spirits are spoken of in the Mosaic laws; and the First Book of Samuel mentions the familiar spirit of the witch of Endor. The genius or *daemovior*, which Socrates and some other celebrated ancients were said to have possessed as a companion, was a species of *familiar*. In modern Europe and Asia, the belief in familiar spirits forms an important feature in the widely spread superstition respecting the magical art. The subject is curiously examined in the article in the *Encyclopædia Metropolitana*.

Family (Lat. *familia*). In Zoology, the group next in value and comprehensiveness above the genus. The term is synonymous with *genus* in the classification of Linnæus, who indicated the different groups of species therein comprehended by numbers instead of collective appellations.

Such divisions of the Linnæan genus occur only in those instances in which an unusual number of species presented themselves to the consideration of the clear-sighted Swede. The progress of modern discovery has added so many new forms to the naturalist's catalogue as to render necessary a corresponding subdivision of most of the Linnæan genera. To these subordinate groups of species distinct names are given, for the sake of convenience; and in order to designate the natural family which these groups compose, the name of the original or typical genus is generally retained with the addition of the Greek patronymic *ida* to the genitive case. Thus e.g. the characters of the Linnæan genus *Mus* are applicable to a vast number of Rodents, which scientific precision requires to be arranged in numerous subordinate groups; these are distinguished by appropriate generic names in modern systems, and the term *Murida* is applied to the *family* which they collectively compose.

Family Council (Conseil de Famille). According to the law of France (Code Napoléon), is composed of six relations, designated by the law, of a minor possessing property, together with the juge de paix. Its peculiar function is the selection of a guardian (*tuteur*) where none has been appointed by paternal or other legal authority. But it has also the right to dismiss a guardian for misfeasance; to sanction the sale of property of the minor; and other very important powers in relation to his management, and the control of his affairs. Some of its acts require confirmation by the tribunals; others are absolute.

Famine (Fr. from Lat. *fames*, *hunger*). When a scarcity of the means of subsistence is so considerable that food is not procurable even by the omission of all other expenditure, famine ensues, and the poorest and most weakly part of the population is sacrificed.

Famines are epidemic in the East. The art of agriculture is imperfect, and the people, generally speaking, living on the cheapest food, and having no export trade of importance, are almost always close upon the margin of possible subsistence. The occurrence of a famine reduces the numbers, and distributing what remains among fewer persons, leaves them the means of life. It is no doubt due to the physiological fact that epidemic disorders of a novel and destructive kind are generated among peoples liable to periodical famines, that the smallpox, the black death or Oriental plague, and the cholera have travelled from the East westwards at different periods.

In England, the latest examples of actual famine occurred in the years 1316, 1317, and 1321. The reason why this country has never been visited by famine for centuries, though often by scarcity, resides in the fact that the habitual food of the English people has been, from the very earliest times in which records of agriculture have been preserved, wheat, the most expensive of all cereals in its cost of production. This fact can be proved by incontestable evidence. Now, where the habit of a people induces the use of a costly kind of food, it is always possible, on the occurrence of scarcity, to substitute a cheaper for the dearer commodity. Population, in short, though it may increase up to the means of subsistence, never increases beyond it; and the limit of population is found in the cost of procuring, in ordinary or average years, the kind of food upon which the people regularly subsist. If, on the other hand, the people are content with the cheapest kind of food, they are always in danger of actual starvation by famine. The Irish famine of 1845 was by no means the only example of such a social calamity, though by far the most appalling for its dimensions and its consequences. Its occurrence is to be fairly ascribed to the practice of subsisting wholly upon the potato, a cumbersome kind of food, carried with difficulty, and capable of being stored only for a very short time; and of course, as supplies from foreign countries can be procured only by acts of exchange, a people which resolves to live on such a food may and does starve in the midst of the plenty enjoyed by other communities.

This economical law, that the risk of famine or the contingency of over-population is in inverse ratio to the charge at which the habitual food of the people may be obtained, has been too much neglected by economists. When the food is costly, the risk is remote; when it is cheaply procured, the danger is near. Hence, much of the reasoning upon over-population and its remedies is vicious, because it omits the consideration of the important questions, What is

the habitual food of the people? and what proportion does the cost of its production bear to the charge at which other kinds of food, available during the pressure of a scarcity, may be obtained?

In the same way, the risk of famine, and even scarcity, is obviated by a wide market. It is clear, in the first place, that the kind of food which costs most to procure at home, and which can nevertheless be grown over a wide area abroad, will, by commanding a better price, be supplied in fuller measure. Hence we may reasonably predict that, though a rise in the price of barley and oats is intelligible, any scarcity in the price of wheat on the hypothesis of free trade is highly problematical. In the next place, the wider the area, the more is the variation in seasons obviated. A bad harvest in one locality is met by a good harvest in another, just as a drought in one region is counterpoised by an increased rainfall in another. In short, the imports and exports of nature, to use an economical parallel, balance one another. The energies, too, of mankind, especially of the Anglo-Saxon race, are yearly making the contingency of even scarcity exceedingly remote. Wheat is imported into this country at highly remunerative prices, even from California, by a five months' voyage; and much of the reasoning of Malthus and Mr. Mill is being refuted or antiquated by facts.

Fan. In applied Mechanics, the name *fan* is generally used to designate the machine used for the purpose of procuring a powerful current of air, for ventilating or for smelting purposes. Fans of this kind usually consist of a shaft, bearing a series of arms, upon which are fixed the sails or blades, working in a close box of a peculiar helicoidal form, and able, through an opening around the bearings of the shaft itself, to receive the air to be thence expelled through a passage which can be directed and regulated as may be required. According to the purposes for which the draught of the fan is needed, the velocity of revolution and the pressure of the air at the outlet are made to vary in every conceivable manner; but as the air when set in motion by the action of a fan follows the laws which govern the imponderable fluids in respect to the interference produced by changes in the direction of the vein, it follows that the inlet pipe should be always placed as near as possible to the working part of the fan, and that the outlet pipe should be as free from curves or abrupt changes of direction as possible.

Fan, Fanners, or Fanning Machine (Lat. *vannus*). A machine for separating the chaff, husks, dust, or other light matters from seeds which are to be preserved for sowing, or for some other purpose in general or domestic economy. The air is put in motion by the revolution of a wheel with leaves or fans instead of spokes, and the current is directed in a stream against the seeds to be fanned; these are placed in a hopper, so regulated as to proportion their descent through the stream of air to the force of the current created by the fan-

FAN PALM

wheel. Before fanners were invented, the process was performed by hand in a manner the reverse of what is now done by machinery: that is, the seeds and refuse to be separated from them were taken up in shovelfuls, and thrown to as great a distance as possible through the calm air. The full-bodied seeds, being the heaviest, fell at the greatest distance, the chaff and other matters falling nearer, according to their degree of lightness. In course of time, a system of screens and sieves was added to the fanning machine. This apparatus, called a *winnowing machine*, not only separates the chaff and other light matters generally from the heavy matters, but parts both according to their bulk and weight: so that the seed comes from the machine fit for being measured up for the market or store room, the various kinds of inferior products being in a state fit for immediate use.

Fan Palm. The name given to various species of Palm-trees, having leaves of a fan-shaped form; but especially applied to *Corypha*, one species of which, *C. umbraculifera*, a native of India and Ceylon, forms a tall tree sixty or seventy feet high, the straight unbranched trunk crowned by a head of enormous leaves with a petiole seven or eight feet long, and the blade of the same length and thirteen or fourteen feet wide, with from ninety to a hundred segments. The species of *Chamærops* are in gardens commonly called *Fan Palms*; and others are furnished in the genera *Sabal*, *Borassus*, *Mauritia*, *Livistonia*, *Thrinax*, &c.

Fan Vaulting. A beautiful form of vaulting used in the perpendicular style of mediæval architecture in England. It has been described by Professor Willis as consisting in vousoirs commencing at the springing concentrically in plan, and proceeding thence towards the centre, cutting into each other, and very frequently finishing with a large pendent, which forms a kind of keystone. The under surfaces are, therefore, curved all ways, and are not plane in any section as the ordinary vaulting; they in some degree resemble pendentives, and meet together in the centre like portions of domes. The finest specimens are at Ely and Peterborough; King's College Chapel, Cambridge; St. George's Chapel, Windsor; and Henry VII.'s Chapel, Westminster.

Fanatic (Lat. *fanaticus*, from *fanum*, a temple). A person who, in matters chiefly relating to religion, adopts, under the influence of his feelings alone, the wildest and most extravagant opinions. The term *fanaticus* was applied anciently to priests of Cybele, Bellona, or other gods, who performed their sacrifices in a wild and extravagant manner; and hence has been bestowed in modern times on those who make pretensions to inspiration, or who conduct their worship with extravagance or licentiousness.

Fancy. [IMAGINATION.]

Fandango (Span.). An air for dancing to, in triple time, and of a quick and lively character. It is the favourite dancing air of the

FARCY

Spaniards, among whom it is of great antiquity. The dancer is usually provided with castanets—a practice borrowed from the Moors—which serve to mark the time more distinctly than a stringed instrument alone would do.

Fanfare (Fr.). A flourish of trumpets: hence the word *fanfaronade* is often used to denote boastfulness.

Fantasia (Ital.). In Music, a species of composition in which the author ties himself to no particular form or theme, ranging as his fancy leads amidst various airs and movements. Rousseau in his definition of this word confines its meaning to extempore composition, and makes this distinction between the *capriccio* and the *fantasia*: namely, that the former is a collection of singular and whimsical ideas strung together by an excited imagination and written down at one's leisure, whilst the latter is an off-hand display of whatever comes across the mind at the instant of execution.

Fantocchini (Ital.). Dramatic representations in which puppets are substituted in the scene for human performers.

Farce (Fr. from Lat. *farceire*, to stuff). In English Dramatic Composition, a short piece of low comic character. The original term seems, like the *Lanx Satura* of the Romans, which gave its denomination to the satire, to signify a miscellaneous compound or mixture of different things. In modern languages it has borne various significations. Certain songs which were sung between the prayers on the occasion of religious worship are said to have been denominated *farces* in Germany, during the middle ages; whence the word appears to have denoted simply an interlude of any kind. In England, the farce appears to have risen to the dignity of a regular theatrical entertainment about the beginning of the last century; since which time it has formed one of the most popular of our exhibitions, being usually performed, by way of contrast, after a tragedy at the national theatres. The farce is restricted to three acts as its limit, but frequently consist only of two or one. Of all the pieces of this class which have successively amused English audiences, none have acquired a permanent literary reputation except those of Foote, in whose farces the license of the theatre in satirising living persons was carried to the utmost height. The *Fabula Atellanæ* of the Romans, which appear to have been short dramatic entertainments of a miscellaneous character, sometimes pastoral, sometimes tragicomic, &c., but not so coarse in plan or diction as the *Mimes* and *Exodia*, which were satirical dialogues in verse between some set characters or stage-buffoons, appear to have filled in some respects the place of the modern farce. On the French stage the *vaudeville* answers to the English farce. [VAUDEVILLE.]

Farcy or Farcin (from Lat. *farcio*, to stuff or cram). A disease of the horse which affects the lymphatics of the skin, either generally producing a distended appearance of the vessels like moles or button, when it is called *he bud* or *button farcy*; or locally, when it is

FARINA

chiefly confined to tropical accumulations in the legs, and is called the *water farcy*. Both forms of the disease are contagious, and difficult to cure. The button farcy is generally removed by burning off the buttons by caustics or a red-hot iron, and by the exhibition of mercury; and the water farcy by the exhibition of mercury alone. Both diseases are sometimes cured by feeding the animal entirely on green food (Blaine's *Encyclopædia of Agriculture*, 2nd edition, page 985.)

Farina (Lat.). Meal or flour, obtained by grinding and sifting wheat and other seeds hence the term *farinaceous food*.

Farinose (Lat. *farina*). In Botany, applied to parts covered with a white mealy substance, such as may be seen in many varieties of the *Auricula*.

Farm (Mr. Wedgwood connects this word with A.-Sax. *feorm*, *hospitality*, lands being let originally on condition of supplying the lord with so many nights' entertainment for his household; but the French *ferme* points with greater probability to the derivation from Lat. *firmare*, denoting lands leased or *confirmed* to a tenant). In Agriculture, a farm is a portion of land, with suitable buildings, fences, and other arrangements necessary for carrying on the business of farming, which is let to the farmer or occupier for rent. Farming is no doubt coeval with the invention of property in land; because we may suppose that when a proprietor had taken possession of a portion of territorial surface, and called it his own, he would require the assistance of various persons to cultivate it; and these persons he could only remunerate by giving them a share of the produce. Hence the origin of what on the Continent is called the *metayer system*—in which the landlord supplies the farmer or tenant with the soil, buildings, and the whole or a certain portion of the stock; while the latter supplies the labour of cultivation and management, and takes as a remuneration the half or some other share of the produce. In process of time, as the tenants or farmers began to acquire capital, they furnished the whole of the live and dead stock, as well as the labour of cultivation and management, and paid the proprietor or landlord a fixed rent in money or produce. To enable the tenant or farmer to do this with the greater security, leases were invented, by which the tenant holding the land for a certain number of years was enabled to lay out money for its improvement at the commencement of his lease, and to receive it back again in the form of increased produce before its termination.

At the commencement of this system of what may be called *free farming*, all farms were undoubtedly of very limited extent; but with the increase of capital and skill on the part of the farmer they have become greatly enlarged. Much has been written respecting the most profitable size of farms for the public; but this may safely be left to the interest of the parties immediately concerned. Whatever size of farm brings in the highest rent to the landlord will

FARMERY

be the best size for the public; because the higher the rent, the greater the amount of the produce that must be sent to market to pay it. That there is a natural limit to the size of farms, there can be no doubt; but what this is, is a different question, and has no connection with the other. It depends on the character of the surface, the kind of farming, and the climate. But though there is a natural limit to the size of farms, which in any given case, can be readily defined, there is no limit to the number of farms that an individual may hold but those of his capital and his skill.

Farmer's Rents. The practice of letting estates at rack rent, i.e. at the full annual value of the land, to persons possessed of sufficient capital for cultivating the soil in the most effectual manner, is almost peculiar to this country, the form of tenure prevailing in other communities being almost invariably that of proprietorship, in small parcels, of lands held at labour rents, or of metayer tenancy.

If the system on which lands are let to farm secures the greatest rate of production at the least cost, it is, from an economical point of view, wholly unimportant that the ownership of the soil should be the property of one man, the use being purchased by an annual payment by another. The political consequences of such a form of tenure are another affair, though they need not be discussed here.

The system of farmer's rents is very ancient in England, having arisen side by side with numerous small properties possessed by free tenants and villeins, in the period subsequent to the great pestilence of 1348. Up to this time, few farmers in the modern sense of the word existed. But the wages of labour, despite the various statutes passed to regulate them, rose so considerably in consequence of the vast mortality of the pestilence, that it was no longer profitable for the lords to manage their estates by bailiffs, or to cultivate them at their own charge. Hence the origin of farmer's rents. At first the landlord advanced certain quantities of seed, stock, and implements, under condition that they should be replaced at the expiration of the term, or, as was more general, paid for at a fixed sum. This custom was, however, speedily abandoned, the great abundance of the harvests during the latter part of the fourteenth century having rapidly put the farmers into easy circumstances. After the middle of the fifteenth century, it would probably be impossible to find any accounts of a character analogous to those which are so abundant in the thirteenth and fourteenth centuries, those namely of the bailiff of a landlord cultivating the soil for the benefit of the owner.

Farmery. The buildings and yards necessary for carrying on the business of a farm. Their situation should be central to the farm lands, in order that the distance from which the crops are brought from the fields to the farmery, and the manure carted from the farmery to the fields, may be reduced to the lowest degree; for when the farm buildings are on one

side of the farm lands, it is evident that the cartage to or from the more distant fields must be attended with considerable loss of labour and time. The main purpose of the farmery is shelter for live stock, and security for the grain and other produce.

Farming. The business of farming, or the cultivation of lands held on lease, necessarily varies in different countries and climates; but one point is common to them all, viz. that no article shall be cultivated which shall not fully remunerate the cultivator or farmer within the limits of his lease. Hence, as few leases in any part of the world exceed twenty years in duration, timber trees are never objects of cultivation by farmers. As a business, farming may be described as that which under ordinary circumstances yields a lower degree of profit than any other mode in which capital and skill can be employed; but where abundance of capital and extraordinary skill are brought to bear on farming, its profits, on an average of a long series of years, may perhaps be not much inferior to those of commerce and manufactures. The great advantages of farming as a pursuit

1. As the articles produced are of the first necessity, there is always a market for them at some price, without much exertion on the part of the farmer; 2. The certainty of always having a home and the means of existence on the farm; and 3. The comparative degree of independence which these circumstances are calculated to create in the mind. These advantages, however, depend much on the length of lease, and on the rent being equitable.

Farming of Taxes. In early and rude systems of finance, before the principles of economical taxation are studied, or indeed cared for, it has always been customary to estimate the probable proceeds of a tax at a certain sum, and to let out the collection of it either to some official especially appointed for the purpose, or to an individual or association at an auction price. The contractor who agreed with the administration to collect the tax, was known among the Greeks by the name *relators*, among the Romans by that of *publicanus*.

Extraordinary powers were given to these officials, and these powers were generally abused. Hence the farmer of taxes was an object of general dislike, and not unfrequently held to be civilly infamous. He was so among the Greeks, for we find an apology for the practice in Aristotle's *Rhetoric*, where, illustrating the topic of what is called parity of reasoning, he makes the contractor say, 'If it is not infamous for you to let the taxes, why should it be infamous for us to farm them?' and everyone knows the disrespect in which the *publican*, or agent of the Roman tax-gatherer, was viewed by the Jews. In Rome the publicani were a corporation, who contrived by means of combination to get the taxes hired to them at moderate terms, and contrived to secure enormous profits on the undertaking. The miserable provincials were forced, in order to meet the demands of the Roman fisc, to

borrow sums of money at prodigious rates of interest from the knights, the regular money-lenders of ancient Rome, and were thus steadily impoverished. The publicani were, indeed, a very important order in the Roman community, for it was to them that the government looked when loans were needed in times of financial difficulty, and they were therefore supported under all circumstances, though the government was well aware of their extortionate proceedings.

The customs in this country have been occasionally let out to farm. In 1282, when the contract was taken by foreigners, they produced 8,411*l.* 1*9s.* 11*d.*; and we read that in 1329 they were farmed again, the produce being less. In the reign of Elizabeth they were farmed by one Smith, and rose from 14,000*l.*, the amount of his first contract, to 42,000*l.*, and ultimately to 50,000*l.* In 1666 they were farmed for 390,000*l.*

It is hardly necessary to say, that such a method of collecting revenue is certain to be wasteful, oppressive, and vexatious, and to create great disaffection. Hence the practice has been almost universally abandoned by modern civilisation.

Farmery. The art of the farrier (Ital. *ferraro*, *ferratore*, from Lat. *ferrum*, *iron*), now generally termed the *VETERINARY ART* [which see].

Farrow (Swed. *farre*, a *boar*, Lat. *verres*). A sow is said to *farrow* when she brings forth pigs; and the pigs brought forth are called a *litter* or *farrow*.

Farthing. A small English copper coin, amounting to one-fourth of a penny; it was anciently styled *fourthing*, as being the fourth of the integer or penny.

Farthingale (Fr. *vertugadin*, Port. *verdugada*: Wedgwood). A name given to the hoop of whalebone used formerly by the ladies of this and other European countries to spread out the petticoat to a wide circumference. It was introduced into England in the reign of Queen Elizabeth, and continued to be used on state occasions down to the commencement of the present century. (Strutt's *Manners and Customs*.)

Fasces (Lat.). In Ancient History, some of the insignia of authority of the chief magistrates of Rome. They consisted of bundles of wooden rods, enclosing an iron axe (called *securis*) so that its head appeared above; and were used as instruments of punishment, the rods being applied for minor offences, and the axe for capital crimes. They were carried before the magistrates by officers called *lictores*, and the number appointed to each varied for the different magistracies. Thus the civic prætors had two, præconsuls and provincial prætors six, the consuls twelve, and dictators twenty-four. The municipal decemvirs also had the privilege of having two fasces carried before them in their own towns.

Fascia (Lat.). In Architecture, a flat member in an entablature, or elsewhere, like a flat band or broad fillet. The architrave, when

FASCIA

subdivided, for instance, has three bands called *fasciæ*; of which the lower is called the first, the middle one the second, and the top one the third *fascia*; or the plinth may likewise be divided into *fasciæ*, which are called according to their number. [ORDER.]

FASCIA. In Botany, a cross band of colour. Hence any surface which is marked by transverse bands of colour is said to be *fasciate*.

FASCIÆ. In Anatomy, the tendinous expansions of muscles. The *fascia lata* is a strong tendinous sheath of the muscles of the thigh.

FASCIÆ. In Astronomy, bright stripes or belts observed on the discs of some of the planets, particularly Jupiter and Saturn. The *fasciæ* or belts of these planets are sometimes broad and sometimes narrow. The less luminous spaces between them have been generally believed to be breaks in the clouds which constantly float in their atmospheres. The clear portions are sometimes of a rose tint. This word is now rarely used. [JUPITER.]

Fascicle, Fasciculus (Lat.). In Botany, a form of inflorescence exactly similar to that called a *corymb*, with the exception that the expansion is centrifugal in place of being centripetal.

Fascicularia (Lat. fasciculus, a bundle). A genus of extinct Zoophytes, whose calcareous cases are in the form of tubes aggregated together in conical bundles, like those of the organ-pipe coral (*Tubifera*). The *Fasciculariæ* are abundant in the English coralline crag formation.

Fasciculate (Lat. fasciculus). In Botany, when several similar parts grow in a bundle from a common point, as the leaves of the larch, the tubers of the *Dahlia*, &c.

Fascination (Lat. fascino, from fascino, Gr. βαρκαίνω—akin to φημι—to enchant). The fact of being charmed, operated upon, or influenced by the look of certain individuals, generally taken in an evil sense. *Fascination* is the power supposed to be possessed by certain persons of working mischief to others by means of a glance of the eye. Among the Romans the god *Fascin* was invoked as a protector against this influence. Virgil alludes to it thus:—

Nescio quis teneros oculus mihi fascinat agnos.
Eleg. 3.

It is to this day a common belief among the vulgar in almost all countries; but probably it is nowhere more generally retained than in Turkey and Italy. In the former country, the Mussulmans deem it necessary to have recourse to a variety of amulets and charms, in order to preserve themselves from the evil eye of an enemy, or of an infidel. In Naples, the evil eye and its fascination (known to them by the name of *gettatura*) are subjects of dread and superstitious precaution among all classes of the people. There is a treatise on fascination by Vairius, prior of a convent at Benevento in that country (1689); another by Frommann (1675).

FAIS

Fascines (Fr.). In Fortification, faggots formed of brushwood, tightly bound together. They are used to revet parapets, and for other purposes.

Fasciolaria (Lat. fasciola, a swathing-band). A genus of Pectinibranchiate Mollusca, dismembered from the rock-shells (*Muriceæ*) of Linnæus on account of the smooth band-like surface of their windings which have not any *varices*, and distinguished from the species of *Fusus* in having plaits on the columella, which are oblique, and consequently spiral.

Fashion (Fr. façon, from the Lat. facere, to make or form). A term used to signify the prevailing mode or taste in any country, the only recognised quality which it possesses being mutability.

Fashion-pieces. In Shipbuilding, those timbers which give shape or fashion to the stern, by forming a connection between the sternpost and the aftermost ribs of the ship's sides.

Fassite. In Mineralogy, a variety of *Augite* from Fass in the Tyrol.

Fastern's Eve. A name, still retained in Scotland, for Shrove Tuesday, or the day immediately preceding the Lenten fast.

Fasti (Lat.). In Ancient History, the records of the Roman state, in which all public matters, military and civil, were registered by the high priest, according to the days on which they took place. The *Fasti* of Ovid is a poem giving an account of the Roman year, and the ceremonies attached to the different days, with their historical or mythological origin. The first six books, containing the first six months of the year, beginning with January, have come down to us; the rest are lost.

Fastigate (Lat. fastigiatus or fastigatus, pined like a pyramid). In Botany, a term led to plants of a pyramidal or tapering it of growth, as exemplified in the branches of the Lombardy Poplar.

Fastigium (Lat.). In Architecture, the slope or fall of any surface or plane; the inclination given to the sides of a building; the gable or the inclined ends of a pediment.

Fasting. In a Theological sense, the abstaining from food as a religious observance, [ASTINCTION.]

The great fast of the Christian Church is that of Lent, from Ash Wednesday to Easter Eve. The number of other fast days throughout the year varies in the Eastern and Western Churches.

For the great fast of the Mahomedans, see RAMADAN.

Fats, Fat or Fixed Oils. The ultimate elements of these substances are carbon, hydrogen, and oxygen. They are common to animals and vegetables: they vary in consistence from thin oil (olive oil) to hard fat (suet). When pure, they are neutral, and leave a greasy spot upon paper, which does not disappear when moderately heated. They are insoluble in water, but more or less soluble in alcohol and ether, and are insipid and inodorous. In vegetables they chiefly occur in the seed and

FATA MORGANA

in the pericarp of the fruit (olive), and are generally obtained by pressure, with or without the aid of heat. In animals, the adipose cells are easily ruptured by heat, which liquefies and expands the fat, so that it runs out and collects upon the water in which the crude fat is boiled. The melting points of oils and fats vary from about 20° to 140°. At high temperatures (500° to 600°) they do not distil unchanged, but evolve acrid products, and are resolved, at a red heat, into inflammable gases and vapours, of high illuminating power. Their specific gravity, which is below that of water, varies much with temperature: the specific gravity, for instance, of hog's lard at 60° is 0.938; in its fluid state at 122° it is 0.892; at 155° it is 0.881; and at 200°, 0.868. Some of these oils are little affected by exposure to air, but gradually become rancid; others absorb oxygen, and form a resinous varnish; they are known as *drying oils*; and when their surface is much extended, as in greasy rags and cotton-waste, this change is sometimes attended by spontaneous combustion. [OILS.]

When the solid fats are subjected to pressure between folds of bibulous paper, they afford more or less of fluid oil; and when the liquid oils are cooled to about 32°, they deposit more or less of a concrete matter. The liquid portion is termed *oleine* or *elaine*, and the solid *stearine*, with which a variable portion of *margarine* is associated. Oleine, stearine, and margarine, are each of them compounds of a distinct *fatty acid*, with a sweet principle, *glycerine*. These acids are the *oleic*, the *stearic*, and the *margeric*; so that oleine is an *oleate*, stearine a *stearate*, and margarine a *margarate*, of glycerine. Besides these, many fats contain distinct volatile acids, such as *butyric*, *capric*, and *caproic acids*, in butter; *lauric acid* in goats' fat; *phoenicic acid* in fish-oil, &c. Oleine may be more or less separated from stearine by ether or oil of turpentine, in which liquids it is much more soluble than stearine.

In the process of *saponification*, the fatty bodies are heated with hydrated alkalies, generally with soda, by which they are decomposed, the glycerine is set free, and *oleates*, *stearates*, and *margarates* of the alkaline bases are formed.

These combinations (*sòaps*) are in their turn decomposed by the greater number of other acids, and the fatty acids are separated. These acids are insoluble in water, but soluble in alcohol and in ether, and are less fusible than the original fats. They are also soluble in oil of turpentine and in benzole, and when free from volatile products are insipid and inodorous. The soaps of alkalies are soluble, but those of the alkaline earths, and of most of the other metallic oxides, are insoluble in water; hence it is that *hard waters* are unfit for washing, in consequence of the earthy salts which they contain, and which give rise to the production of insoluble soaps. [SOAP.]

Fata Morgana (Ital.: called also *Castles in the Air*), the spectacle being

to be under the influence of the Queen

FATHERS OF THE CHURCH

of the Fairies, the *Morgan la Fay* of popular legends). A remarkable phenomenon of *mirage* or atmospheric reflection mentioned by different authors and travellers as seen in the straits of Messina, especially in the vicinity of Reggio. It exhibits in the air, over the surface of the sea, multiplied images of the objects on the surrounding coasts. It is thus described by Minasi: 'A spectator on an eminence in the city of Reggio, with his back to the sun and his face to the sea, and when the rising sun shines from that point whence the incident rays form an angle of about 45° on the sea of Reggio, sees upon the water numberless series of pilasters, arches, castles, well delineated, regular columns, lofty towers, superb palaces with balconies and windows, villages and trees, plains with herds and flocks, armies of men on foot and horseback, all passing rapidly in succession on the surface of the sea.' There can be little doubt that this description, which has been frequently copied, and even admitted into treatises on optics, has received considerable embellishment from the aid of the imagination. Captain Smyth, in his excellent work on Sicily, observes, 'I never met with a Sicilian who had *actually seen* anything more than the loom or "mirage" consequent on a peculiar state of the atmosphere; but which, I must say, I have here observed many times to be unusually strong.' (*Memoir descriptive of the Resources, Inhabitants, and Hydrography of Sicily and its Islands*, p. 109.) [MIRAGE.]

Fatalism. The belief in an overruling fate or destiny which annihilates free will and controls all human actions. For the philosophical doctrine of fatalism, see NECESSITY; for those religious opinions which have assumed a similar character, see ELECTION and PREDESTINATION.

Fate. [DESTINY; NECESSITY.]

Fates (Lat. *fatum*, that which is spoken, as the Gr. *moira* is akin to Lat. *mo*, to speak). In Mythology, the three sisters Clotho (spinster), Lachesis (allotter), and Atropos (unchangeable), whose office it was to spin the destinies of men, and break the threads at their appointed hour of death. They were called *Parce* by the Latins. Their Greek name was *Μοῖραι*, i.e. the *Dispensers*. [MOIRA.]

Fathers of the Church. The early Christian writers whose works have thrown light upon the history, doctrines, and observances of the primitive church, and who are thereby entitled to be regarded as witnesses to the faith and practice of the first believers. The period to which the list may be extended is, of course, arbitrary. St. Bernard in the twelfth century is generally styled the last of the Fathers. The writers of the first century, or who were contemporary with the first disciples, are distinguished by the term *Apostolic Fathers*. The general character of the writings of these celebrated men, their trustworthiness as witnesses, their authority as judges in matters of doctrine and discipline, and the utility of studying their works, have been discussed by divines with far more of prejudice and the

spirit of system than the love of truth. A voluminous controversy was carried on upon this subject, towards the end of the seventeenth century, between some Protestants, chiefly of the Calvinist churches, who attacked the Fathers, and others, both Protestant and Catholic, who defended them. On the former side, two works of some notoriety were produced: Daillé's *Treatise on the Use of the Fathers*; and Barbeyrac, *Morale des Pères de l'Eglise*. Among many answers, may be cited that of Cellier to Barbeyrac, 1718. In England, Burnet, Hill, Peter Allix; Reeves (*Apologies of the Early Fathers, with Dissertations*, 1709), took part in it. The Benedictines of Paris, in the seventeenth century, published valuable editions of the principal Fathers, both Greek and Latin. Nourry, a learned member of that order, published an *Apparatus* to Despont's great collection, the *Bibliotheca Patrum*, in which much information is collected.

Fathom (A.-Sax. fæthm; Dutch, vadem). An English measure of length, equal to two yards or six feet, and founded on the distance between the finger-points when the arms and hands are extended horizontally. It is the unit of length in all matters of nautical surveying.

Fattening Domestic Animals. The object of fattening is to accumulate flesh and fat for sale. The means used by all fatteners of domestic animals, whether quadrupeds or poultry, are: preventing the animals from taking exercise, and tempting them to eat by the variety and quality of their food. The best system is called *box-feeding*, by which a dry and warm lair is provided along with opportunity for a minimum of exercise.

Fatty Acids. Fats and fixed oils are composed of an acid or acids united with the base glycerine. The glycerine may be displaced on boiling the fat with any stronger base such as potash or soda, the acid uniting with the latter to form *soaps*. When a soap is heated with strong acids such as hydrochloric or sulphuric acid, the base is removed and the fatty acid obtained in the free state.

The term is also sometimes made to include acetic and formic acids, which, though not themselves oleaginous, yet belong to the same chemical series. [FATS.]

Fauces (Lat.). The posterior part of the mouth, terminated by the *pharynx* and *larynx*.

Faujasite. A hydrated silicate of alumina, lime, and soda, from Baden; named after Faujas St. Fond.

Fault. In Geology, a fracture of strata, accompanied by a sliding down or a thrusting up of the deposits on one side of the fracture to a greater distance than the other. The broken beds are thus no longer continuous; and as these fractures cause frequent interruptions of work in mining, they have long attracted attention, and are recognised under different names wherever underground operations are carried on. The disruption is often accompanied by a wide gap filled up with clay, or

even stones and rubbish. The synonyms of *fault* are *slip*, *throw*, *trouble*, *drop*.

To the geologist the fault is a proof of elevation or depression, and often points to the direction of the elevating force; but as strata of great value (such as coal and ironstone) have very often been subject to this accident, it is a matter of importance in practical geology to understand the mechanics of the event, in order that a lost bed may be followed. In the annexed diagram, B may represent a bed broken asunder and separated by a *dyke*, A (the dyke being a wide fissure accompanying a fault).

Whether the thickness of the dyke or fault (A) is great in proportion to that of the bed faulted (as represented in the diagram), or a mere line as sometimes happens, it is always possible to lay bare a little of it, either at the surface or at the point where it is reached underground. If when thus laid bare, the angle made by the plane of the bed with the plane of the fault is more or less than a right angle, the position of the lost part of the deposit, above or below the part worked, may be discovered by a simple observation. The direction of the line that makes an obtuse angle will be that which points to the broken bed. Thus, if in the diagram the fault is cut from the right, the bed beyond is at a lower level; if from the left, it is at a higher. This will always be the case, from the mechanical conditions of the problem. There are some apparent and a few real exceptions, owing to peculiar and complicated mechanical conditions of the disturbance. The remembrance and application of this law are very important in coal-mining.

Faults are of various magnitude; some of the smaller faults are only a few inches in drop, others a foot or two. Both these may be due to contraction and cracking of the bed, and not to elevation; for when a mass is broken, a different pressure of any kind will produce a minute change of level. Such small faults are called *slips*. Larger faults are of all magnitudes up to many hundred fathoms; but it must not be forgotten that the enlargement of a fissure once made may take up an almost indefinite time, and be carried to almost any extent very gently, the removal of the rising sides being in progress during the whole upheaval, and no violent movement taking place at any time.

Faults are best known in the coal measures, because in these beds their influence is most important. They are common, however, in all rocks, and in brittle rocks may be noticed by thousands in every quarry. The larger faults are not confined to mountain regions, some of

FAUNA

the most important occurring in countries now nearly level. No doubt in these cases there has been enormous denudation during the growth of the fault.

Occasionally the contents of the interspace connected with faults, being impermeable to water, serve as backs to prevent water from running along sandy or loose beds, and may thus be useful to the miner. They are, however, not less frequently troublesome and mischievous. So, also, if they have sometimes brought to the surface minerals that would otherwise have been lost, they have perhaps quite as often carried beds of minerals away.

Fauna. The animals peculiar to a country constitute its *fauna*. The term is derived from the Fauni of Roman Mythology. [FLORA.]

Faunus. An Italian rural deity resembling the Grecian Pan, and, like him, having the gift of prophecy. Mention is sometimes made of several Fauni, who were represented, like the satyrs, with the horns and feet of goats. There was an annual festival instituted to their honour, called *Faunalia*.

Fausse-braye. In Fortification, a low rampart round the body of the place, parallel to the main rampart.

Faux (Lat. the old nom. sing. of *fauces*). In Botany, the orifice of the tube of the corolla, the tube being formed by the confluence of the petals.

Favose or Faviculate (Lat. *favus*, a honeycomb). In Botany, honeycombed; cellular.

Fayalite. A native silicate of iron from the island of Fayal.

Fayence. [FAIENCE.]

Fidelity (Lat. *fideltas*). In Feudal Law, the oath of fidelity (Fr. *féauté*) taken by every tenant on admission to be true to his superior lord. General *fidelity* is that due from the subject to the prince; special *fidelity* from tenant to mesne lord. *Fidelity* is said to differ from homage in being due to every new lord. The oath, as administered in England, was fixed by stat. 17 Edw. II. c. 2; but it has long been obsolete, although, in copyhold tenements, the memory of it is still preserved by the customary entry of respite of *fidelity* on the admission of a new tenant.

Festivals or Festivals (Lat. *festivus*, from *festus*, *festal*). Days set apart by the church, either for the celebration of the most remarkable events connected with the scheme of redemption, or to commemorate the actions and sufferings of such persons as have been most instrumental in carrying forward the designs of God for the salvation of mankind. This was a practice of the primitive church; but in process of time (as early as the fourth century) the great number of names which had been introduced into the calendar rendered its observation both burdensome and superstitious. The church of England retains the festivals of the nativity, circumcision, manifestation, the death, resurrection, and ascension of Christ, the purification of the Virgin and the annunciation (or Lady-day), Whit-Sunday in honour of

FEATHERS

the Holy Spirit, and Trinity Sunday. Besides these, the most remarkable of the apostles and the evangelists are commemorated on their respective days; and one day is set apart for the remembrance of all the saints. A few names of later saints were still retained at the Reformation, as a compromise with the prejudices of the people, but no services are connected with them. The saints' days of the former class are called *red-letter*, those of the latter *black-letter days*, from the colour in which they were originally printed in the church calendar. Festivals are either movable or immovable; the former depending upon Easter, the latter being fixed to certain days of their respective months.

Feather-edged. In Architecture, a term which is applied to a board which has a triangular or rather a trapezoidal section; one edge being thinner than the other. The term is also applied to stone coping or other work of a similar kind.

Feathering. In Rowing, the act of turning the blade of the oar, while emerging from the water preparatory to being thrown forwards for another dip, from a vertical to a horizontal position. The oar thus turned offers less resistance to the wind or to the water should waves strike it, and has a more elegant appearance.

Feathers (Dutch, *veder*; Ger. *feder*; Swed. *fjäder*). This term, in Zoology, is restricted to those productions of the dermal system which form the most exterior covering of birds, and which consist of the following parts, viz. a quill (*calamus*), a shaft (*rhachis*), and vanes (*pogonium externum et internum*).

The quill is that part of a feather by which it is attached to the skin; it is nearly cylindrical in form, hollow, and semi-transparent, possessing in an eminent degree the opposite qualities of strength and lightness. The end which is implanted in the skin is more or less obtuse and is pierced by an orifice called the *lower umbilicus*. At the opposite end, where it is continued into the shaft, and just at the meeting of the two lateral vanes, there is another orifice, called the *upper umbilicus*. The cavity of the quill contains an imbricated series of conical capsules, united together by a central pedicle, forming the membranous remains of the original formative pulp.

The shaft is quadrilateral, with a smooth convex surface, and an opposite concave surface traversed by a longitudinal impression continued from the upper umbilicus. It is covered by an outer layer of firm horny material like that of which the quill is formed, and this encloses a soft elastic substance called the *pith*.

The vane consists of *barbs* and *barbules*.

The barbs are attached to the sides of the shaft, and consist of narrow elongated plates, arranged with their flat sides towards each other, and their margins in the direction of the external and internal sides of the feather. By this disposition they offer much resistance to being bent out of their plane, though readily yielding to any force acting upon them in the line of the stem.

FEATHERS

The barboles are minute and often microscopic processes, given off from either side of the barbs, and arranged in a single series, just as the barbs are placed with reference to the shaft. In true feathers, they are short, stiff, and curved in opposite directions on opposite sides of the barb; and the concavities of one series of barboles interlock with those of the adjoining barbs, so that the whole vane presents a continuous and resisting surface, as in the quill-feathers of most birds. When the barboles are long and disjointed, the feather is termed a *plume*; in the long dorsal plumes of the peacock, the barboles themselves are ciliated.

In a few instances, as the apteryx and ostrich, the feathers are simple. In most birds each feather is complicated by a part termed the *accessory plume*. This is usually a small downy tuft; but it varies as to its size both in different species, and even in the feathers of different parts of the body of the same bird. In the body-feathers of the hawks, grouse, ducks, gulls, &c., the accessory plume is generally well developed, and acquires in some species a size equal to that of the feather from which it is produced. In the emeu this is the case with the whole plumage, and the quill of each feather supports two shafts. In the cassowary there are two accessory plumes, one of which is equal to the size of the original feather, the other is much smaller.

Feathers vary in form, size, and function, in different parts of the bird, and have accordingly received distinct names in ornithological science. Thus the feathers which surround the external opening of the ear, and which serve to augment the intensity of sound, are termed the *auriculars*. Those which lie above the scapula and humerus are called the *scapulars*. The small feathers which are arranged in imbricated rows upon the bones of the antibrachium are called the *lesser coverts* (*tectrices primæ*); those which line the under or inner side of the wings are the *under coverts*. The feathers which lie immediately over the quill-feathers are the *greater coverts* (*tectrices secundæ*). The largest quill-feathers of the wing, which arise from the bones corresponding with those of the hand, are termed *primaries* (*remiges primoræ*); those which rise from the ulna, towards its distal end, are the *secondaries* (*remiges secundariæ*); those which are attached to its proximal extremity are the *tertiaries* (*remiges tertiariæ seu parapterum*). The quill-feathers which grow from the phalanx commonly called *thumb* form what is termed the *bastard wing* (*alula spuria*). The quill-feathers which are implanted upon the os coccygis are called *rectrices*.

The development of feathers is always preceded by that of down, which constitutes the first covering of young birds. Each down-fascicle consists of a small quill, supporting a bunch of equal-sized finely-ciliated filaments. The down-fascicles are succeeded by the feathers, which they guide, as it were, through the skin; and the feathers of each succeeding plumage

FEDERAL GOVERNMENT

serve, during the moult, as the *gubernacula* of those which follow.

The mechanism concerned in the formation of a feather is, as might be expected, of a very complicated character. It consists of vascular parts which secrete the material, and of moulds or capsules, in which the fluid material is thrown into the proper form; the whole is enclosed in an outer sheath, which is protruded with the new-formed feather from the skin, and which, becoming dry and friable from contact with the atmosphere, crumbles away, and leaves the feather free to unfold its beautiful and complicated structure.

For the laws which regulate the varieties and changes of plumage, see *INDUMENTUM*.

Feathers, in reference to their chemical composition, may be regarded as indurated albumen; their ultimate elements being carbon, hydrogen, oxygen, nitrogen and sulphur. The ash of feathers, especially of birds which live on grain, contains, however, a large proportion of silica. The colours of feathers are due to peculiar organic pigments which may be separated by proper solvents; the beautiful play of colours which some of them exhibit is referable to a decomposition of light analogous to that produced by mother-of-pearl and similar striated surfaces.

Febrifuge (Lat. *febris, fever*, and *fugo, I drive away*). A remedy which cures or relieves fever: the term is commonly applied to medicines used in the treatment of agues.

February (Lat. *Februarius*). The second month of the year, containing twenty-eight days in common years and twenty-nine in leap years, the intercalary day being given to it as the shortest month. For the position of February in the ancient Roman calendar, see Sir G. C. Lewis, *On the Astronomy of the Ancients*, p. 46.

Fecials or **Fetials** (Lat. *fetiales*). The Roman heralds, whose peculiar office it was to declare war and conclude peace. The former office they performed with the following ceremonies: They were first sent to demand redress; if it was not given within thirty-three days, they returned to the confines of the hostile state and threw a bloody spear within them, having proclaimed war according to a given formula before not less than three adult witnesses. The *fecial*, who took the oath in the name of the Roman people in concluding a treaty of peace, was called *Pater Patratus*. The college of *fecials*, said to have been instituted by Numa, is supposed to have been borrowed from the Greeks. They were probably twenty in number.

Facula. [*FACULA*.]

Federal Government (Lat. *foedus, a league or treaty*). A government formed by the union of several sovereign states, each surrendering a portion of its power to the central authority. But the amount of the power thus surrendered varies in different federations. Thus the government of the German empire as it existed before the French revolution, and that of the

United Provinces of the Netherlands, were both termed *federal*; and the Swiss cantons, under the present Swiss constitution, have retained more of their individual sovereignty than those of the United States of America, inasmuch as they have no permanent federal executive body, and their legislature, or *diet*, is little more than a meeting of delegates with full powers from separate republics to consider certain common concerns. [DWR.] The theory of the American constitution, on the contrary, recognises not only unity in respect of foreign relations, but also a common legislature, which alone has the right to impose certain taxes (such as customs) and to regulate the management of waste or public lands throughout the Union; as well as a permanent common executive, consisting of the president and his cabinet, charged with the superintendence of those branches of administration which regard the whole community. This being the theory of the federation, the events of 1860-61 precipitated the discussion of the great question of principle which had been raised more than thirty years before by South Carolina: whether a state could lawfully secede from the Union. It was contended, on the affirmative side, that the constitution does not expressly prohibit secession; on the negative side, that the constitution does not contemplate it as a possibility, and that the supposition is in itself destructive of the basis of the Union—arguments which may be, as they have been, reproduced with every variety of ingenuity; but the logic of the strongest is certain in such cases to prevail. (St. Croix, *Des Anciens Gouvernements Fédératifs*; Droysen, *Hellenismus*; Freeman's *Federal Government*.)

Fedia. This genus of *Valerianaceæ* yields the Corn Salad or Lamb's Lettuce, *F. olitoria*, a salad herb, much used on the Continent under the name of *Mache*. It is sometimes called *Valerianella*.

Fee Simple (Ger. *fehde*, Mod. Lat. *feodum*: hence the derivation of *fee* in all its meanings). In Law, an estate of freehold of inheritance in lands, tenements, or hereditaments. Tenant in fee simple absolute, or, as it is more briefly expressed, in *fee*, is one who has the fullest power of disposing of his tenement which the law allows; and not being disposed of by him either in his lifetime or by devise, it descends to his heirs general.

An estate to a man and his heirs qualified by a condition or limitation capable of abridging it, as an estate to A and his heirs on condition of paying a sum of money on a stipulated day, and if he fail to do so then to another, is termed a *fee conditional*; or, with less propriety of language, a *fee simple conditional*.

Fee Tail. In Law, arose out of the statute De Donis, 13 Edw. I.; which restrained the alienation of lands and tenements by one to whom they had been given, with a limitation to a particular class of heirs. A gift, for instance, to a man and the heirs of his body, constituted before the statute a fee simple conditional, which

could be alienated as soon as a child was born to the donee: after the statute it became inalienable, until more latitude was given by the invention of certain refined fictions of law.

A deed creating an estate tail is properly called a *gift*, and the giver and receiver the *donor* and *donee*. Estates tail are *general*, where only one person's body is specified from which the issue must be derived; *special*, where both the progenitors are marked out, as in a gift to A and the heirs of his body to be begotten upon B. It may also be descendible to all the issue, or to male or female issue; in which case estates are said to be in tail male or in tail female. Half-blood is no impediment in the descent of an estate tail general. Where lands and tenements are given to a man and his heirs in special tail (by a wife named in the grant), and his wife dies without issue, the husband is tenant in tail after possibility of issue extinct; and his estate is in most respects equivalent to one for life only.

Estates tail being contrary to the general policy of the law, legal ingenuity was taxed, in early times, to invent modes whereby they might be defeated; i.e. whereby the donee might destroy the special limitations of the gift, and acquire an estate in fee simple without incurring forfeiture. This was done by the fiction of *common recoveries* (of which the validity was established in the courts in the reign of Edw. IV.), and by that of fines, recognised by statute (4 Hen. VII. c. 24, 32 Hen. VIII. c. 36). A simpler process has been substituted for these ancient contrivances by the Act 3 & 4 Wm. IV. c. 74, by which the process of *barring an entail* was rendered easy. Donee in tail may now grant leases for twenty-one years, under 19 & 20 Vict. c. 120.

Fee-farm Rent. In Law, a rent charge in fee, issuing out of an estate in fee of at least one quarter of the value of the land at the time of its reservation. Some authorities consider the amount as immaterial. No grant in fee farm can be made since the statute of quia emptores.

Feelers. Organs fixed to the mouth of insects, generally less than the antennæ, and often jointed. [PALPS.]

Fees. In Law, perquisites allowed to ministers of justice, fixed either by Act of Parliament or ancient usage.

Feline Courts. [VERMIN COURTS.]

Felis (Lat. *a cat*). The name given by Linnæus to the genus of *Feline* or carnivorous quadrupeds, of which the common cat is an example. The essential characteristics of this genus are the strong, sharp, retractile talons with which all the four feet are armed, and the corresponding destructive nature of the dentary organs. These consist of six small incisors in each jaw, the exterior ones larger than the rest; two long and strong canines, bounding the series of incisors in the lower jaw; and two in the upper jaw of still greater length and strength, conical, sharp-pointed, slightly incurved, and separated from the incisors by an

FELIS

interval corresponding in size with the summits of the inferior laniaries, which always pass, when the mouth is closed, in front of those of the upper jaw.

The molar teeth are four in number on each side of the upper jaw, and generally three on each side of the lower; the two anterior in each series are smaller than the third, and furnished each with a single conical pointed middle process. The third molar is the largest in both jaws, and presents a very characteristic form in the lower one being compressed, and terminating in two sharp-pointed trenchant triangular lobes, which play upon the inner surface of three corresponding lobes of the tooth above; the appulse of the lower carnassial or sectorial tooth is checked, and the upper gum defended, by an internal tubercle in the upper sectorial. The fourth molar in the upper jaw is placed within the posterior margin of the third, and presents a simple transverse slightly convex plate, affording additional surface for the inferior sectorial to work against. The claws and teeth above described are better adapted for the seizure and destruction of living animals than are those of any other mammalia; and the power of wielding these weapons is enjoyed in a corresponding degree of perfection. There are no quadrupeds in which the muscles of the jaws and limbs are more fully developed. The teeth, as we have seen, are few, though formidable: those of the lower jaw occupy only its anterior half; the rest of the jaw consisting chiefly of a broad and high coronoid, and a strong angular process for the implantation of the immense muscles destined for its movements. The skeleton of the feline animals presents a light but well-built mechanism: the bones, though slender, are extremely compact; the trunk, having to contain the simple digestive apparatus requisite for the assimilation of highly organised animal food, is comparatively slender, and flattened at the sides. The muscular forces are thus enabled to carry the light body along by extensive bounds, and it is thus that the largest felines generally make their attack. When the impetus of the spring is added to the stroke of the paw, the lion or tiger has power to fell an ox or smash the skull of a man at a single blow; and as the strength of the neck corresponds with that of the jaws and limbs, they are enabled to bear away with ease animals bigger and heavier than themselves. It fortunately happens that the feline animals have not the instinct of sociality, otherwise what could withstand a troop of lions or tigers hunting in concert like a pack of wolves?

The feline animals or cats constitute a well-defined and circumscribed genus. The leopards, panthers, jaguars, and tigers, are the most typical or truly feline species; in these the beauty of colouring, sleekness of skin, elegance of form, craft, suspicion, bloodthirstiness, agility under excitement, and sloth during repletion, are most strongly manifested. The lion combines more robustness of body with the feline attributes; and his pre-eminent stature receives

an air of nobility and grandeur from the mane that decorates his head and neck. He has the credit, too, of a greater share of boldness and generosity than the other cats. His vocal organs also exhibit a modification of structure not present in the other felines, by which he has the power to utter his tremendous roar. Among the felines, one group is characterised by the shortness of the tail, and the tuft of hairs on the tip of the ears; this includes the lynxes.

The cheetah, or hunting leopard, *Felis (Cynailurus) jubatus*, deviates from the true feline character chiefly in the half-retractile condition of the talons and the upright carriage of his body; and with these physical modifications is combined so much of the canine disposition as enables this species to be used in packs for the purposes of the chase.

The middle-sized cats (*Leopardus*), which lurk in the branches of trees, as the leopards, ocelots, &c., have a fulvous ground colour, broken by irregular dark spots; a marking which admirably adapts them for concealment amidst foliage. A similar relation of adaptation to the peculiar theatre of their destructive habits may be traced in other species. The tiger, for example, which prowls on the ground and creeps stealthily towards his victim between the stems of the trees and plants of the jungle, has his bright ground colour interrupted with black vertical stripes. The lion, which traverses the parched deserts of Africa, and lies in wait to intercept the antelopes which bound in troops from one oasis to another, would be rendered too conspicuous if his tawny hide were ornamented by the stripes or spots that characterise the feline livery; these, therefore, which are obvious enough in the earlier periods of his existence, become obliterated as he attains to maturity. A smaller feline species, the puma, or American lion, which plays its part in a corresponding theatre of the New World, presents a similar uniformity of colour.

The feline animals bring forth from two to six young ones at a birth. The domestic cat is the most fertile; a circumstance which arises from the abundance of food, shelter, and protection, consequent on her alliance with man. But, as has been frequently remarked, this, of all domesticated animals, is the least servile or restrained; and though instances of personal attachment are not wanting, the affection of the cat is rather to the house than to its owner. There are many singularities in the nature of the cat, which perhaps our comparatively limited acquaintance with the other felines leads us to regard as peculiar to this species. She is remarkably nervous, and readily startled; gives out the electric spark when her fur is rubbed contrary to its direction, as is very conspicuous when this is done in the dark. Under the excitement of fear, the same effect is produced on the long hairs of the tail as if a stream of electricity were transmitted through them, and they all stand out from the surface to which they are attached, giving the tail an appearance

FELLIC ACID

of treble its usual thickness; at the same time the back is raised, and the body drawn into its smallest compass. Cats are attracted by peculiar odours, and exhibit a violent fondness for catmint and valerian, rubbing their noses and rolling themselves in the latter with signs of great and uncontrollable excitement. Cats are very cleanly, are fond of warmth, and seek a soft place for their repose. They express their satisfaction by a peculiar soft vibrating noise, called *purring*.

Fellie and Fellinic Acid (Lat. *fel, gall*). Products obtained from bile.

Felling Timber. In Arboriculture, when a full-grown tree is cut down it is said to be *felled*; but this term is never applied to young trees or bushes, undergrowth, or hedges, which are said to be *rooted out*, or *cut over*. Much has been written respecting the proper season for felling trees; some arguing in favour of midwinter, and others in favour of midsummer. The question principally turns upon the quantity and the value of the soft or outer wood in the trunk of the tree to be felled, known by foresters and carpenters as the *sap*. As this sap or outer wood is the only portion of the trunk in which the sap or juice of the tree circulates, it is evident that if no value be set upon it, the tree may be cut down at any season; because the truly valuable part of the trunk, the mature timber, is impermeable to the sap in its ascent through the soft wood, and is therefore in the same state at every season of the year. On the other hand, where much value is attached to the soft or outer wood, or where, as in the case of comparatively young trees, the greater part of the trunk consists of sap wood, felling ought to take place when there is least sap in the course of circulation. This season is without doubt midwinter, which, all other circumstances being equal, is unquestionably the best season for felling timber; the next best being midsummer, when the sap is chiefly confined to the young shoots, the circumference of the soft wood, and the bark. In general, all the soft woods, such as the elm, lime, poplar, willow, &c., should be felled during winter: hard woods, like the oak, beech, ash, &c., when the trunks are of large size, and valued chiefly for their heart wood, may be felled at any time.

Fellow (Old Eng. *felaw*, Norse *felagi*; a partner in goods). In the colleges of the English universities, and some other collegiate institutions, the superior members of the foundations are so termed in general. In some, however, all members of the foundation are fellows from their admission. The usages of different foundations in the two universities vary so materially, that no general account will apply equally to all. The fellows are, in general, graduates; and were under the old systems elected either on free competition, or according to limitations fixed in the statutes of foundation. But most of these latter limitations have been abolished at Oxford since the recent reform of that university. Most fellows are obliged to abandon their fellowships if they do

FELLO DE SE

not take orders at a certain period: there are, however, lay fellowships in both universities. Fellowships are also vacated in the universities by marriage; and by the acceptance of preferment in the church from the college, or in some instances of other preferment of a certain value. From among the resident fellows are selected for the most part the governing officers and tutors of the colleges. The principal or head of the college is generally elected either by the whole or a select body of the fellows. There is a distinction in some colleges between senior and junior fellowships, in point of emolument, which does not exist in others. At Cambridge there is, or was, also a distinction between foundation fellowships and bye or appropriation fellowships; the former only, in most colleges, entitling the possessor to college offices. The value of fellowships varies greatly; nor do they always maintain the same amount, being generally dependent on corn-rents. The advantages obtained by the fellow are partly in income; partly, if resident, in free lodging and allowances towards board. There are fellowships of the value of 500*l.* or 600*l.* per annum, and others of 100*l.* or less; but a large proportion may be said to average from 150*l.* to 300*l.* a year. *Fellow* is also the general title of members of learned academics and societies in England.

Fellowship or Partnership. A rule in Arithmetic, of considerable use in balancing accounts among partners in trade. Considered as an arithmetical process, it is simply a method of dividing a number into parts which shall have given proportions to each other. Fellowship is either simple or compound. To simple fellowship belongs a question of this sort: 'A contribution of 20,000*l.* is levied on three towns, and each is required to pay in proportion to the number of its inhabitants. Now the first contains 2,000 inhabitants, the second 3,000, and the third 5,000; what sum must each contribute?' This question is obviously the same as if it had been required to divide the number 20,000 into three parts, having the ratios of 2, 3, and 5, which is done by dividing 20,000 by the sum of 2, 3, and 5, that is by 10, and multiplying the quotient by each of those numbers separately; the several results are the sums required.

Compound fellowship is when the parts into which the given number is to be distributed are proportional to more than one set of numbers. This is usually called *fellowship with time*, because in distributing the profits of a mercantile transaction carried on by several partners the share of each must be proportional, both to the amount of the capital which he contributed and to the time during which it was employed. It must therefore be proportional to the product of these two. Both cases, it may be remarked, belong to what is more correctly termed *distributive proportion*.

Felo de Se. In Law, one who is found by the coroner's jury to have laid violent hands on himself, or occasioned his own death feloniously.

This verdict occasions forfeiture of chattels, real and personal; but not of lands of inheritance. One found *felo de se* was formerly buried in the king's highway, with a stake driven through the heart; but since 1823 (4 Geo. IV. c. 52), such bodies are privately buried in a burial-ground, between the hours of nine and twelve at night.

Felony (a word of uncertain derivation. Sir H. Spelman derives it from the word *fee* or *fief*, and the Teutonic *lohn*, *reward* or *price*; that which costs or forfeits land: more probably from the same root with the verb *to fail*). In Law, in the general sense, comprises every species of crime which occasioned at common law the forfeiture of lands and goods. Treasons, therefore, are, strictly speaking, felonies, though in common language distinguished from them. The term *felony* appears, in feudal law, to have been synonymous with forfeiture to the feudal lord. The general punishment attached to felony at common law was death; and if any statute, even now, makes a new offence felony without specifying the punishment, the law implies it to be capital. But some species of felony were not thus punishable at common law; and the gradual operation of altered opinion upon our code has removed this punishment from all but a few. The principal species of felony are: 1. Offences against the person, such as murder, manslaughter, rape, &c.; assault with felonious intent, that is with intent to injure the sufferer in a greater or less degree. The highest of these offences against the person are still punishable by death. Some of them, as common assaults, &c., are only misdemeanours. 2. Of offences against property, the great body is comprehended under the ancient appellation of *larceny*. 3. Embezzlement. 4. Burglary. 5. Malicious mischief to property, arson, riotous demolition of churches, chapels, houses, &c. 6. Forgery. 7. Numerous offences of a public nature (many such, however, amount only to misdemeanour): (1) Either against the king and government, as treason, sedition, embezzlement of the king's stores, &c.; (2) Against public justice; (3) Against the public peace; (4) Against public trade; (5) Against public police and economy. Under this head also are to be ranked some offences relative to game, while others come under the description of larceny. The Acts relating to felonies and criminal law generally were consolidated and amended by a series of statutes of 24 & 26 Vict.

Felsite. A compact variety of Labradorite, which with Hornblende forms the greenstone of Siebenlehn in the Erzgebirge.

Felspar. In Geology, the mineral felspar is the basis of so many rocks and is distributed so widely in various forms, that it almost ranks as a rock. It is the basis of Trachyte, one of the most important volcanic products, and is not unfrequently met with massive as *felsstone* or *felsstone porphyry*. The modifications of felspar recognised under these names are metamorphic rocks, but it is not always easy to say

whether they are derived from or pass into the condition of the crystalline mineral. Hardly any simple minerals except quartz and limestone are found in such large masses as felspar.

FELSPAR. In Mineralogy, a name given to several minerals varying much in appearance, and presenting numerous and complicated crystalline forms. They are mixtures of silicate of alumina with silicates of soda, of potash, or of lime, and of other bases. Orthoclase or Common Felspar is of various tints of white and red; it forms an ingredient of granite and other rocks.

The name Felspar is derived from the German *Feldspath*, or *field-spar*, which was probably given to it in consequence of the crystals being sometimes found lying loose on the surface of the ground. Kirwan states the derivation of the word to be from *fels*, a rock; from the common occurrence of the mineral in granite.

Felt (Ger. *filz*). A material formed by interlacing flocks of wool, or hair, without spinning or weaving, so that the texture is spongy and absorbent, until the spaces have been filled up with some substance introduced in the state of a solution, or until the surface has been closed by means of the fulling mill. Asphalted felt is used as a material for temporary coverings or roofs; and a compound of caoutchouc and felt is employed as a kind of floor-cloth.

Felting. The process by which different kinds of fur or wool are blended into a compact texture for the manufacture of hats. The anatomical or structural peculiarities of the different hairs or furs are much concerned in the perfection of the felt; they must be such as to enable them to interlace and intertwine with each other. Hare and rabbit fur, wool, and beaver, are the chief materials used; they are mixed in proper proportions, and are tossed about by the strokes of a vibrating string or bow till they become duly matted together.

Felucca (Span. *saluca*, Ital. *feluca*). A small vessel propelled by oars and lateen sails, used chiefly in the Mediterranean and in the adjacent waters for coasting voyages. Before the introduction of steam, feluccas were often used as gunboats, for which the small size and the power of propulsion by oars as well as sails peculiarly fitted them.

Femme Covert. In Law, a term borrowed from the French to signify a married woman.

Femur (Lat. *a thigh*). In Architecture, the interstitial space between the channels of the triglyphs in the Doric order. These femora are sometimes called the *legs* of the triglyphs.

FEMUR. In Vertebrate Anatomy, the first bone of the leg or pelvic extremity. In Entomology, the third joint of the leg, which is long, and usually compressed.

Fen Lands. Lands, the subsoil of which is constantly in a state of saturation with water, and the surface liable to be overflowed by rivers or streams during spring or autumn. The soil of these lands is generally black, light and rich, to the depth of two or three

FENCE

feet; and as the surface water readily filtrates through it to the subsoil, fen lands generally produce bulky crops of grass and corn. As they seldom have any natural outlet for drainage, this is generally performed by machinery, and when this is the case few lands are more productive. Till lately windmills were employed for draining the English fens; but steam is now frequently used as the moving power, and the advantages to the cultivator are immense because he can lay his lands dry at the season when it is most convenient that they should be so, whereas the operation of the windmill is always a matter of chance. For an account of the Fens in England, see *British Statistics* and Mc'Culloch's *Geographical Dictionary*, art. 'Bedford Level.'

Fence (Fr. *défense*, as the English *route* from the Fr. *déroute*: Wedgwood). Any continuous line of obstacle interposed by art between one portion of the surface of land and another for the purpose of separation or exclusion. The kind of obstacle or material differs according to the animals which are to be separated, excluded, or confined, and the nature of the soil and situation. All fences are either live or dead, or a compound of these. Live fences are hedges; that is, rows of shrubs placed close together, and pruned on the sides, so as to form a sort of living wall. Dead fences are either stone walls, mounds of earth, or structures of wood or of other materials raised above the ground's surface, or open ditches excavated in it. The latter are sometimes filled with water. Mixed fences are those in which some kind of dead fence is used with some kind of live fence; for example, a ditch with a bank of earth on one side, or a ditch with a wall or a hedge on one side: the latter being the commonest of all fences. The introduction of fences into agriculture was about as great an improvement in the progress of that art, as that of the principle of the division of labour into the art of manufacture.

Fend Off. The Sea term for pushing off a boat or any heavy body to break the shock or avoid contact. So also a *fender* is a cushion of yarn, oakum, and rope, inserted between the sides of two boats, or of a boat and any other object, to prevent contact and rubbing.

Fender Pile. A pile fixed in front of a wharf or a river wall, to protect it from abrasion by floating bodies, such as ships, ice, or timber. They need not be carried, therefore, much lower than the water-line, and they are usually made of whole timbers.

Fenestra (Lat. *a window*). In Anatomy, the term is applied to certain holes in the osseous or petrous capsule of the internal organ of hearing; one on the outer wall of the labyrinth, which is filled by the base of the *stapes*, is called the *fenestra ovalis*; a second, at the base of the cochlea, is called the *fenestra rotunda*, and is separated by a membrane from the cavity of the tympanum. [EAB.]

Fenestrate (Lat. *fenestratus*, with windows). In Entomology, signifies the naked

FERLE

hyaline transparent spots on the wings of butterflies.

Feniculum (Lat. *fennel* or *finkel*). The genus of Umbelliferous plants to which belongs the Fennel and Finnochio. It has finely dissected leaves and yellow flowers; much like *Anethum*, to which it is further allied by its laterally compressed fruit. *F. vulgare*, a wild plant found in dry chalky soil near the coasts, is the Fennel of the gardens, and the fruits both of this and of *F. dulce* yield an aromatic oil.

Fennec (Abyssinian). A species of *Canis*, also termed the Zerdä, in which the ears are excessively developed, and whose anatomical structure bears some resemblance to that of the viverrine *Carnivora*.

Fennel. [FENICULUM.]

Fennugreek. The *Fanum gracum*, a leguminous annual herb, called by botanists *Trigonella Fanum gracum*, because formerly made into hay in Greece. It was cultivated by the Romans, and is still occasionally met with in the agriculture of the south of Europe. Both the herb and the seeds are strongly scented, the odour indicating the presence of coumarin.

Fcoffment. In Law, a species of conveyance. It was in early times the public and solemn mode of alienating lands and tenements in possession, and was performed by a deed, accompanied by livery of seisin; which last was the delivery of the land itself, effected by certain symbolical acts and customary words. As secret conveyances to uses gradually prevailed, feoffments fell comparatively into disuse. The grantor is termed the *feoffor*, and the person receiving the *feoffee*.

Feræ (Lat. *wild beasts*). The name given by Linneus to the order of Mammalia comprehending those which subsist more or less exclusively on the flesh of other animals. They are characterised by having three kinds of teeth, incisors, canines, and molars; unguiculate extremities, without an opposable thumb on the fore foot, but with the power of rotation in the forearm. This order corresponds with the *Insectivora*, and the *Plantigrade*, *Digitigrade*, and *Pinnigrade Carnivora* of Cuvier's *Carnassiers*.

Feræ Naturæ (Lat. *of wild nature*). In Law, a term applied to animals, such as foxes, wild ducks, &c., in which no one can claim property.

Fergusonite. In Mineralogy, a crystallised compound of columbic acid and yttria with a small quantity of zirconia, and of oxides of tin, cerium, iron and uranium. It has hitherto been found only in Greenland.

Feræ (Lat.). In Roman Antiquities, solemn religious festivals. The most celebrated were the *Feræ Latine* (Latin holidays), celebrated on the Alban Mount by all the states of Latium in common. This festival is said to have been originally instituted by the second Tarquin. At first it lasted for one day only; but in process of time it was extended to four; it was observed by the consuls regularly before they set out for their provinces.

FERINES

Ferines (Lat. *ferinus*). The English equivalent of the *Carnassiers* of the system of Cuvier; but generally employed to designate the group corresponding with the *Feræ* of Linnaeus, and excluding the bats (*Chiroptera*), which form the first family of Cuvier's *Carnassiers*. [PNEUMATICS.]

Fermat's Theorem. One of the most important in the science of Arithmetic. Its discoverer, Fermat, is said to have been in possession of a proof (*Fermati Opera Mathematica*, Tolosæ 1679), though Euler was the first to publish its demonstration (*Comment. Arith.* Petropoli 1849). The theorem is susceptible of two equivalent enunciations: First, If p be a prime, the $(p-1)^{\text{th}}$ power of every number prime to p will, when diminished by unity, be exactly divisible by p . Thus $25^4 - 1$ is exactly divisible by 7. Thus enunciated, Fermat's theorem may be regarded as the fundamental proposition of the arithmetical theory of the residues of powers. Secondly, The binomial congruence $x^{p-1} \equiv 1 \pmod{p}$ has always $p-1$ incongruous roots when p is a prime number. The congruence in question, therefore, has its maximum number of roots [CONGRUENCES], which latter constitute, of course, a complete system of residues prime to p . It is from this point of view that Fermat's theorem may be justly regarded as the basis of the whole theory of congruences.

Amongst the demonstrations of the theorem which have appeared since the one above referred to, those most esteemed were given by Lagrange (*Mém. de l'Acad. de Berlin*, 1771), Dirichlet (*Crelle's Journal*, vol. iii.), Binet (*Jour. de l'École Polytech.* cah. xx.), and Poinso (t) (*Réflexions sur la Théorie des Nombres*). Euler's first demonstration is a very simple one, and is the one generally given in elementary treatises on the subject.

Another theorem, distinguished as *Fermat's last Theorem*, has obtained great celebrity on account of the numerous attempts that have been made to demonstrate it. The theorem asserts that $x^n + y^n = z^n$ is irresolvable in integers for all values of n greater than 2; and although it was enunciated by Fermat two centuries ago, no complete demonstration has yet been given. The least incomplete demonstration was given by Kummer in *Crelle's Journal*, vol. xl., and Liouville's *Journal*, vol. xvi. The theorem has been established, at all events, for all exponents up to 100.

Ferment (Lat. *fermentum*, from *ferveo*, I boil). The substance which is essential to the process of fermentation. It is either naturally present in the fermentable juice, as in the grape; or it is added, as in the manufacture of beer, where yeast constitutes the ferment. Ferments are of an albuminous or glutinous character: the presence of nitrogen seems essential in their composition; hence they are classed by chemists among azotised compounds. Their modus operandi is still unexplained.

Fermentation (Lat. *fermentatio*). By fermentation, we understand the conversion of

FERMENTATION

an organic substance into new compounds, in presence of a ferment. Hence there are various kinds of fermentation, designated according to their products. In *vinous fermentation*, sugar, or any substance capable of being easily converted into sugar, is resolved into carbonic acid and alcohol, 45 parts of sugar yielding 22 of carbonic acid and 23 of alcohol. But pure sugar, dissolved in pure water, has no tendency to undergo this remarkable change, except under the influence of a nitrogenous principle called a ferment. It was observed by Gay Lussac that when fresh grape-juice was collected in a vessel containing carbonic acid, no fermentation took place, although all other circumstances were favourable to this process. When, however, the juice was exposed to air and a proper temperature, it rapidly fermented, and when once this fermentation had commenced, it continued until the saccharine matter was decomposed. There appears, therefore, to be present in grape-juice a substance which by contact with oxygen becomes a ferment; and further, that the saccharine juice of the ripe grape does not ferment, because the access of free oxygen is cut off by the epidermis of the fruit.

In the process of *brewing*, the fermentation of the *sweet wort* is accelerated by the addition of a ferment in the shape of *yeast* or *barm*, which occasions the rapid conversion of the saccharine matter of the wort into alcohol and carbonic acid, and tends at the same time to the formation of new yeast.

It has been shown by Mitscherlich, that the actual contact of the particles of the yeast with the dissolved sugar is essential. He suspended a wide glass tube, the bottom of which was closed with bibulous paper, in a jar of a solution of sugar, the tube being itself filled with the same solution. Some yeast was then put into the syrup contained in the tube, where it soon induced fermentation, and the alcohol there formed passed through the pervious bottom, and, together with carbonic acid, diffused itself in the surrounding liquor: but the actual phenomena of fermentation—namely, the decomposition of the sugar and the formation of alcohol and of carbonic acid—were limited to the syrup in the tube containing the ferment, while the sugar in the outer vessel remained unchanged.

Quevenne found that yeast which had been deprived of all matter soluble in water, still retained its power of exciting fermentation, and that the active part of yeast is composed of minute vesicles or globules, which during fermentation germinate in the saccharine liquor. According to Andral and Gavarret (*Ann. Ch. et Ph.*, 3ème sér., viii. 399), there are two species of germs contained in yeast, which may be separated by diluting it with water: in a few days globules fall to the bottom of the vessel, forming a grey pulverulent deposit which is extremely active in producing alcoholic fermentation; but at the same time a film forms upon the surface of the liquid, which consists of germs (of *Penicillium glaucum*) having no such

FERN ROOT

power: these latter germs become *filamentous*, while the true producer of alcoholic fermentation always retains its *globular* form. According to Mitscherlich, the active part of yeast which remains after it has been washed with water, consists of: Carbon, 47.0; hydrogen, 6.6; nitrogen, 10.0; oxygen, 35.8; sulphur, 0.6.

Of this yeast (in the dry state) from two to three parts are required for the decomposition of one hundred parts of sugar; and if there is excess of sugar, it remains unchanged after the fermentation. That portion of the yeast which remains in the form of a deposit after fermentation is over, and which is inefficient as a ferment, appears, when examined under the microscope, to consist of the ruptured cells, and is not susceptible of vegetation; so that during the fermentation of sugar, a certain portion of the yeast-plant dies, and is decomposed, the living plant being required to sustain the fermentative process. If more yeast be present than is required for the decomposition of a certain quantity of sugar, the deposit which is in that case formed, consists partly of broken and partly of entire cells, and the latter retain their power of inducing fermentation. It further appears that that portion of the yeast which has become inert as a ferment, has lost the greater part, if not the whole, of its nitrogen; and one of the results of the changes which ensue during saccharine fermentation appears to be the formation of ammonia, traces of which may be detected amongst the gaseous products.

What is called *German yeast* is yeast which has been washed and dried at a low temperature. It is chiefly obtained from the distilleries of Holland, and is largely imported into England. Boiling water destroys the fermenting properties of yeast; but unless boiled so long as to have its chemical nature entirely changed, it re-acquires a fermenting power on exposure to air.

Sugars differ in the readiness with which they undergo fermentation. Pure cane-sugar (*sucrose*, $C_{12}H_{22}O_{11}$) does not readily ferment; grape-sugar (*glucose*, $C_6H_{12}O_6$) is easily fermented, but the process takes place most readily in fruit-sugar (*fructose*), represented by $C_6H_{12}O_5$. And it is probable that both cane and grape sugar pass into fruit-sugar before they undergo the change. When fermentation is complete, 100 parts of fruit-sugar are resolved into 51.12 of alcohol and 48.88 of carbonic acid, so that the ferment adds nothing to and removes nothing from the elements of sugar. Vital, chemical, and dynamic hypotheses have been proposed to account for the *modus operandi* of the ferment in effecting the changes, but as yet we remain ignorant upon this subject.

Fern Root. The root of the *Aspidium Filix mas*, or male fern. About two drachms of the dried root, in powder, followed up by a brisk purge, is occasionally given as a vermifuge. It was Madame Nouffer's celebrated specific.

Ferns. [FILICES.]

Feronta. In Botany, this name of an Italian deity (akin to Tellus) is given to the Wood-apple or Elephant-apple of India, *F.*

FESCENNINE VERSES

elephantum, a tree which belongs to the order *Aurantaceae*. A transparent gum, sent to this country as East Indian gum arabic, flows from the trunk when wounded; and the fruit, which has a pulpy flesh, has a beneficial action in cases of dysentery and diarrhoea.

Ferret. [MUSTELA.]

Ferric Acid. An unstable tetroxide of iron, not known in the free state: it is formed in combination with potash.

Ferriocyanogen or **Ferridcyanogen.** A compound of two atoms of iron and six of cyanogen, which, in combination with three atoms of potassium, forms the *ferridcyanide of potassium*, or *red prussiate of potash*.

Ferro-hydrocyanic Acid. A compound of three atoms of cyanogen, two of hydrogen, and one of iron. It is the *ferro-chyasic acid* of Mr. Porrett, the term *chyasic* being composed of the initials of carbon, hydrogen, and azote, which are the ultimate elements of hydrocyanogen.

Ferrocyanogen. A compound of one atom of iron and three atoms of cyanogen; or one of iron, six of carbon, and three of nitrogen; in combination with two atoms of potassium, it constitutes *anhydrous ferrocyanide of potassium*, the crystals of which include three atoms of water. This crystallised ferrocyanide of potassium is generally known under the name of *yellow prussiate of potash*.

Ferrugo. In Botany, a disease of plants, commonly called *rust*. It is caused by the parasitic fungus called *Trichobasis Rubigo vera* (formerly *Uredo*), and one or two allied species, of the order *Pucciniae*. While confined to the leaves, it does comparatively little injury; but it becomes formidable when it attacks the chaff and seed. It generally accompanies over-luxuriance.

Ferry (Ger. and Sax. *fahren*, to pass over). In Law, a right arising from royal grant or prescription to have a boat to carry men and horses across a river, and to levy reasonable toll. The land on both sides ought to belong to the owner.

Ferula (Lat.). A genus of Umbelliferous plants with yellow flowers, and thin flat fruit resembling that of the parsnip. The species are chiefly natives of Persia and the Mediterranean region. The plant from which the principal supply of Assafetida is obtained, formerly included in *Ferula*, is now referred to *Narther* [NARTHEX]; but *F. persica*, a smaller plant than the foregoing, is said to yield some portion of it. From *F. orientalis* and *F. tingitana* are obtained African ammoniacum. [AMMONIACUM.] Many of the species are handsome plants, with very large leaves divided into an infinite number of small variously shaped segments, and producing tall stems which bear large umbels of yellow flowers. They are called *Giant-fennels* in gardens.

Fescennine Verses (so called from Fescennia, an Etrurian town, where they first had their origin). In Roman Antiquities, rude extemporaneous pieces of poetry recited by the youth of Latium and Etruria at rustic festivals,

FESCUE GRASS

especially at harvest home, with gestures adapted to the sense. They consisted principally of railery and playful rustic abuse, and are chiefly remarkable as having given rise to Satire, the only class of poetry of native Italian growth. [SATIRE.]

Fescue Grass. A valuable grass for meadows and pastures. In deep rich soils somewhat moist, *Festuca pratensis* is considered one of the most bulky and nutritive of all grasses; but in poorer soils it is equalled, if not surpassed, by the rye grass (*Lolium perenne*) and the meadow foxtail grass (*Alopecurus pratensis*). The meadow fescue grows to the height of between two and three feet; but the sheep's fescue (*F. ovina*) and several other species seldom grow above a foot in height, and are chiefly sown on sheep pastures, and used to lay down lawns and grassy surfaces to be mown in pleasure grounds. All the cultivated fescues are perennials, and most of them natives of Britain. *F. heterophylla*, *Halleri*, and *valesiaca* are among the foreign species which are cultivated for their produce.

Fess (Lat. *fascia*, a wide belt). In Heraldry, one of the ordinaries. It is bounded by two horizontal lines across the escutcheon, equally distant from the *fess point* or centre of the escutcheon. A fess not reaching to the sides of the escutcheon is said to be *couped* (cut) or *humetty*. The diminutives of the fess are the *bar*, the *closet*, and the *barulet*. A fess with a barulet on each side of it is said to be *cotised*. A fess removed to the top of the escutcheon is termed a *chief*, and held to be an honourable augmentation.

Festoon (Fr. *feston*). In Architecture, a carved representation of a wreath or garland of flowers, or leaves and fruit, or of all of them interwoven together; they are thick in the centre, and diminish gradually towards each extremity, where they are fastened, and often turned over.

Fetials. [FETIALS.]

Fetish or Fetishism. The word *fetish*, said to be derived from the Portuguese, appears to have been brought into common usage by the writings of some travellers on the western coast of Africa. It is now comprehensively employed to signify any object of worship not representing a living (or rather perhaps a human) figure; thus excluding idols, properly so called. Fetishism is the worship of material substances, and prevails very extensively among barbarous nations, and especially those of the negro race. Among the latter, tribes, families, and individuals have their respective fetishes; which are often objects casually selected, as stones, weapons, vessels, plants, &c. &c. [ONKAR; POSITIVISM.]

Fetlock (quasi *footlock*, whence the derivation). In the *Mantege*, a tuft of hair growing behind the paster joint of horses; hence the joint where it grows is called the *fetlock joint*.

Fettered. In Zoology, a term applied to the feet of animals when they are stretched backwards and appear unfit for the purpose of

FEUDAL SYSTEM

walking; or when they are concealed within the integuments of the abdomen.

Fettstein (Ger. *fat stone*). [ELAOLITE.]

Feu (Lat. *feodum*, *sief*). In Scottish Law, is used in contradistinction to *ward-holding* or military tenure, to signify that holding where the vassal makes a return in grain or money in lieu of military service. The *feu contract* is that which regulates the giving out of land, as between superior and vassal; the rent paid being termed the *feu duties*.

Feudal System. A body of institutions of a peculiar character, introduced into Europe by the German and Gothic tribes, which prevailed for a long period, and has left important traces of its existence in most European countries. The words *sief* and *feud* are both, it is conjectured with much probability, corruptions of the Græco-Latin term *emphyteusis* (pronounced *emphytefsis*), signifying a contract whereby an individual acquired the enjoyment of a piece of land without the absolute property in it. Hence by contraction came *fief* or *sief*, and by the addition of a neuter termination *fevodum*, *feudum*, *feodum*. Another derivation, recently suggested, is from the Irish *fuidhur*, *fuidh*, signifying, in the Brehon Laws, a stranger who enjoys land within the domains of a clan, and the tenure by which he enjoyed it. The English word *feud* (quarrel or strife) is of an entirely distinct origin, being the same with the German *fihrde*. The German equivalent for *sief* is another original word, *lehn*.

It is clear that feudal usages were absolutely unknown to the ancient Romans; but among that people, and especially in the later times of the empire, there existed certain customs which were analogous in appearance, although not in origin—such as the establishment of military colonies on the frontier, where the tenant of land was a soldier, and liable to be called into active duty; and the cultivation of great part of the empire by *coloni*, a distinct class of men, raised above the condition of the slave, and yet bound to render services to the proprietor, and in some instances annexed to the soil. The barbarians therefore in many instances adapted the conventional language and the laws of Rome to their own native customs; thus producing a confusion of idiom and practice, of which a better instance cannot be found than the fact already mentioned, that the word *feud* itself is derived from a legal term of the Greek empire.

The immediate result of the conquest of Gaul, Italy, and Spain by the various barbarian tribes, was the division of the lands (except such portions as were left in the possession of the Roman cultivators and only rendered liable to tribute) between all the armed men of the nation. The shares were undoubtedly unequal even in the earliest of these divisions; but however differing in point of wealth, all the free proprietors were equal in rights: all were held liable to serve with the national force when called into the field; all had a voice, at least nominally, in the making of laws and in the choice of a sovereign. These free citizens are

FEUDAL SYSTEM

called by various names in the legislation of the different tribes; the Lombard title of *arimannus* (chren-mann, man of honour, or bear-man, warrior) seems to have been the most permanent. Such, however, was the general constitution of the kingdoms of the Lombards in Italy; the Franks in Gaul; the Visigoths, Ostrogoths, and Burgundians; and of the various states which grew up within the limits of Germany itself, after the confusion occasioned by the great migrations had passed away.

The decay of these aristocratic republics, brought about by nearly the same causes which operate in undermining all systems founded on equality of rights and classes. The constant vicissitudes to which these governments, subject naturally raised up among the citizens some more powerful than the rest, and converted a great body of the freemen into dependants upon these. The dukes, counts, and other great men, became the actual controllers of the community: the free citizens, wherever unable to associate for mutual protection, were subject to innumerable vexations. From the earliest times, and before the fall of the Roman empire, it had been customary among the Germans for the princes and chief men to be attended by a select body of faithful companions, whose dependence on them, and services due to them, were recognised and fixed by general usage. This custom, under the new circumstances of the Germanic and Gothic kingdoms, acquired peculiar force. It became an object of ambition to the chieftains to have as many dependants as possible. With this view, every species of vexation was exercised by them towards the unprotected *arimannus*, to induce him to abdicate his own independence, and enroll himself under their command. During the wars and confusions of the eighth and ninth centuries, the foundations of the feudal system were laid by this personal dependence assuming gradually the character of a territorial dependence also. The *arimannus* was induced to surrender up his free or allodial lands to the king or count, and became his *liegeman* (*fidelis*), *entrustation* (our English word *trust* comes from the same source), *vassal*, or *man* (homo, whence *homagium*, homage), receiving back his lands to hold of the superior. This process can only now be traced by insulated documents and historical facts; but, arising out of the same circumstances in most countries of Western Europe, it took in all of them nearly the same course. It is ably developed by Hallam (in his first chapter on the *Feudal System*), and Meyer (*Institutions Judiciaires*, livre i.).

The success and energy of Charlemagne arrested for a time the decomposition of the old society; his empire extended over nearly all those portions of Europe which afterwards became feudal; and his various laws (in the end of the eighth and beginning of the ninth century) present a remarkable picture of what may be called the state of transition from the allodial to the feudal system. We find in them that the free proprietors, or *arimanni*,

still formed a very numerous body; and that the exigencies of military service fell most heavily upon them. They were obliged to serve at their own cost; while the counts, &c. brought their vassals to the field at their own expense. These laws are full of the vexations endured by the former class from the powerful military chieftains. On the other hand, the practice of attaching individuals to the person of the sovereign or superior by the grant of lands (*benefices*), and the obligations imposed on the inferior by the grant, are clearly developed. The distinction between lands *allodial* (held in *franc alev* without feudal superior) and *feudal* lands (though the latter term was not yet used) is as marked as at any subsequent period. But *benefices* were not yet hereditary: and it is doubted by the most learned writers, whether they were generally or frequently precarious and revocable, or not.

The decay of Charlemagne's empire, and the disasters of the two centuries which followed his reign, completed the formation of the feudal system. The great step by which that change was completed was when the *benefices* or *fiefs* became, like the former *allodial* properties, hereditary. There can be little doubt that this change was merely the result of those dissimilar circumstances of civil and barbarian war which during that period relaxed the slight bonds of the Carolingian monarchy, and rendered every man as far as possible dependent on an immediate superior, and independent of a central authority. The earliest express creation of an hereditary *fief* is considered to be the donation of the duchy of Aquitaine to Eudes and his heirs by Charles-le-Chauve. The great vassals established their families permanently in the lands which they held of the *sec* or royal domain: their liegemen, in turn, were gratified by acquiring the same right in their own subordinate *fiefs*. There can be no doubt that the nobility of modern Europe owes its origin, in general, to nearly the same period and the same causes: those families which succeeded in acquiring extensive *fiefs*, and preserving them for several generations, became noble by prescription. In the meantime, the *arimanni*, or allodial proprietors, found that their condition became worse from generation to generation; they were loaded with services and dues until, in the tenth century (as is shown by Meyer), the term *arimannus* became synonymous with exaction. But although the feudal system became so generally prevalent, that the maxim 'Nulle terre sans seigneur' (importing that lands were presumed feudal until the contrary was shown) became generally received, yet in France and Germany the allodial proprietors never became wholly extinct. In some districts of the former country the maxim was reversed, and lands were presumed allodial. (Hallam.)

The law of Conrad, the Salic, in Lombardy (1039), contains all the main features of feudalism: the *Assises de Jerusalem* and other compilations show, that in a century more it had

FEUDAL SYSTEM

been invested with all the refinements of a legal system.

By the principles of this system, the king was, in the last resort, proprietor of all the feudal lands of his kingdom. Those who were enfeoffed of lands directly from the crown, and owed homage and service to the king, were termed *tenants in chief* (in capite), &c. These, again, enfeoffed other inferior tenants, who held immediately of them; and this practice (called *sub-enfeudation*) might be carried on through several gradations. Thus the same individual was a *vassal* or dependant of the crown, and *lord* or *suzerain* with reference to his own vassal who held of him, also termed *mesne* or mediate lord, a term which comprehended both these relations. But although all perfect fiefs resembled each other in their theoretical character, and particularly in their great attribute of military service; yet, in point of fact, tenants holding immediately of the crown stood in very different degrees of subordination. Thus, in France, the great vassals (the dukes of Normandy, Brittany, &c.) were immediate tenants of the crown, but in effect almost independent of it; while they exercised much stricter sovereignty over their own immediate tenants. But other lands, being the demesne of the crown itself, were held of it by lesser tenants in chief, who stood to the king in the same close relation as the vassals of the great feudatories did to them. Thus the government of France, at the period when the feudal system was in greatest vigour, was that of a collection of independent sovereigns, of whom one, the king, had a certain supremacy over the rest, but each, within his own domains, exercised an equal authority; and such was, in theory at least, the constitution of every feudal kingdom. The ceremonies used in conferring a fief were chiefly three: 1. *Homage*, by which the vassal owned the lord's supremacy; but *homage per paragium*, or simple homage, was unaccompanied by any feudal obligation; *homagium ligium*, or liege homage, implied such obligations: the former only was rendered to the king by the great feudatories above mentioned. (Hallam's *Middle Ages*, ch. ii. part i.) 2. The oath of *fealty*. 3. *Investiture*, or the conveyance of feudal lands, actual or symbolical. The chief obligation of a feudal tenant was military service; but the laws which regulated this essential part of the contract were so various, that it is not possible to give any comprehensive description of them. In some places every tenant was obliged to serve personally for his fief, whether large or small; in others (as England), the land was divided into a certain number of equal parcels, from each of which a soldier's service was due: the term of service was also variously regulated by custom. The conflicting rights of superior and inferior lords to the vassal's military service were also never satisfactorily adjusted. When feudality was in its most flourishing state, he commonly followed the banner of his immediate superior, even against the crown; but with the progress of the royal power, his obligations

were gradually transferred to the king as lord paramount: military service was in most cases rendered commutable, in process of time, for an amercement in money. [ESQUAGE.] There were other inferior obligations which attached to the military tenures, commonly called *feudal incidents*. These were chiefly: 1. *Reliefs*; i.e. sums of money paid to the lord by tenants of full age on taking fiefs by descent. 2. *Fines* upon alienation, which were sums paid on alienating a fief; a privilege which was only gradually acquired by feudal tenants, being contrary to the principles of the institution. 3. *Escheats*; i.e. the reversion of the fief to the lord, on failure of the tenant's heirs or forfeiture. 4. *Aids*; sums paid by tenant to the lord, on certain specified occasions. And to these may be added the feudal rights of *wardship* (by which the lord, in some countries, had the custody of his tenant's person, and the enjoyment of his lands until he was of full age) and *marriage* (by which the lord had the right of disposing of such ward's land in marriage, or, if the marriage were rejected, to a sum of money equivalent to the marriage, i.e. as much as it was presumed the party seeking the marriage would have given the lord for the alliance). Forfeiture of the fief to the feudal lord was incurred by the tenant's violating any of the original conditions of fealty, homage, and military service. But the vassal was protected from the unjust aggression of the lord by that which seems to have been an inherent and necessary condition of the feudal system; the judgment, namely, of his peers, without which such forfeiture could not be incurred—supported by the right of private warfare, which in the last resort was the resource both of the lord to enforce obedience from the vassal, and the vassal to protect himself against his equal or his superior. On failure of heirs, the fief fell or escheated to the lord. Fiefs holden by military tenure were, strictly, *proper fiefs*. There were also a great variety of tenures by rendering particular stipulated services, created, for the most part, in comparatively late times, which were also deemed feudal in their character, and constituted *improper fiefs*; such were, especially, tenures by the performance of menial or other personal services, from which arose the English *Grand Serjeanty*. [SERJEANTY, GRAND AND PETTY.] All these tenures were of a higher or noble character; but in some countries large portions of the land were held either immediately of the king, or mediately of feudal lords, by base or inferior tenures. Such lands were styled *fiefs roturiers* in French jurisprudence; in English, this class of tenures was comprehended under the common term of *socage*, which comprised both tenures in *free* or common socage, and those in *villain* socage, from which are derived tenures in *ancient demesne*. [SOCAGE.]

The division of ranks under the feudal system corresponded in theory, although not precisely in practice, to the territorial division of lands according to their tenures. Those who held their fief by knight-service were the original

FEUDAL SYSTEM

nobility of the soil; nor has the class of gentry, in most countries, any other origin. The bearing of arms, the distinctive character of surnames, &c. &c., became afterwards, in course of time, the distinctive marks of the class of nobility, which no longer adhered so closely to the soil from which it sprang. Thus in France we find that a noble might, in later times, hold a *fief roturier*, while a *roturier* might hold a proper *fief*; although, in such a case, services such as were rendered by the gentry were of course commuted. But it may be in general observed, that almost the whole soil of France, north of the Loire, was under noble tenures; in the south only were free tenants, not noble, a numerous class. In many parts of Germany the distinction between *adeliche güter* (noble fiefs) and *bauer güter* (peasant fiefs) has been only recently effaced, or still subsists: in Prussia it was abolished in 1807. In England the course of the feudal system was somewhat different; the class of free tenants in socage was far more numerous and influential: hence the yeomanry of England formed a body of men to which a parallel could hardly be found in any other country. The burghesses, or inhabitants of towns, constituted in feudal realms a class apart; and their communities were either really, or by fiction, emancipated by royal charters from the tenure by which they were supposed to hold their land either of the king or some mesne lord. Lastly, the lowest class of the population consisted of serfs or villeins, attached to the soil in many instances; but whose state varied so greatly under different circumstances as to render it impossible to give any general description of their condition.

Such is a very brief and general outline of the complicated system of rights and duties which bears the historical name of feudal. It is necessary, however, to add, that this system assumed very different shapes in the different countries in which it prevailed. France was the country in which feudalism had, if not its origin, at least its greatest extension, and was most nearly reduced in practice to its theoretical form. Up to the fall of the Carolingian empire, that country must be regarded as an aggregate of provinces, inhabited by different nations, and governed by a variety of laws, but acknowledging the sovereignty of a monarch whose power was more or less obeyed, according to his own personal talents and other casual circumstances. After the separation of France and Germany by the treaty of Verdun in 843, a succession of feeble princes and the invasions of the Normans almost broke up the slender frame of the French monarchy. The governors or masters of extensive provinces, who had by this time secured to themselves the hereditary sovereignty of their respective benefices, became independent within their own limits: when feudal royalty was continued under the Capetian kings, these ranked as the great vassals of the crown. Their powers have been classed by Mr. Hallam under five heads: 1. The right of coining

money; 2. That of waging private war; 3. The exemption from all public tributes except the feudal aids; 4. The freedom from legislative control; and 5. The exclusive exercise of original judicature in their dominions: of these, the fourth was the most characteristic of the French system. No general legislative power, vested in an assembly of the nation, seems ever to have existed in France as a whole. This circumstance, which in the first instance seemed to the great vassals a security for their independence, proved in the end the cause of their decay; as, with the gradual increase of the royal powers, the legislative authority of the king himself, in the absence of any recognised national council to assist him, acquired continually increasing force. Meanwhile, the extraordinary power of the great vassals in France in some degree weighed down that of the inferior nobility; the ties of feudal subjection, weakened in the highest relation (i.e. between the great vassals and the crown), were much stronger between the great lords and the lesser barons, *châtelains*, or *vassalors*, who depended on them. The king, according to the establishments of St. Louis, could not declare any new law in the territory of his baron without his consent, neither could the baron in that of his *vassalor*; but, in a partial point of view, the king and the baron, within their respective demesnes, exercised a much more real sovereignty than that which the former possessed over the latter. It was about the reign of Philippe-le-Bel, in the beginning of the fourteenth century, that the feudal system, which had lasted up to that time from its establishment in the tenth without material innovation, was in effect overthrown, and the king of France began to be in reality master of his kingdom. This change was chiefly brought about by the extension of the king's juridical power by means of the parliaments; and lastly by the convocation of the States-General, as the representative body of the whole nation. The greater fiefs were reannexed in the course of events to the crown, with the remaining power and privileges of their lords.

There can be no question that feudal principles prevailed to a considerable degree in the polity of the Saxons in England; but when that country was conquered by the Normans, the latter imported with them the entire system, already invested (in the eleventh century) with a legal and regular character. Hence, while feudalism grew up from the circumstances of society in France, it may be said to have been transplanted, as to most of its details, into England from a foreign soil. The land was parcelled out, as in France, between higher feudatories and inferior tenants holding of them by knight-service. But two circumstances chiefly produced the very different shape into which the system ultimately resolved itself: 1. The existence of the great body of freemen of Saxon descent, who were neither reduced into villanage, nor deprived of their lands, nor yet ennobled by being ranked

FEUILLEA

along with the Norman military tenants. 2. The permanent national council, which seems to have been everywhere a peculiarity of the Norman system of government, and which, by taking cognisance of matters pertaining to the general interests of the realm, at once controlled the power of the king and that of the great barons as single and independent chiefs. Thus the country remained, even in the most troubled period of the Plantagenet dynasty, in constant union under some central authority; and the feudal principles were modified, both by the common law of the land, and also by various statutes, of which that commonly styled by its first words 'Quia Emptores,' passed in the reign of Edward I., which put an effectual stop to all further *sub-infeudation*, was perhaps the most effectual.

In Germany, as well as France, the feudal usages seem to have grown into a system under the sovereignty of the Carolingian emperors. But in that country, owing, perhaps, partly to the constant danger from foreign invasion on the eastern side, which kept the people more together under the central authority, the sovereigns never lost, during the dark period of the ninth and tenth centuries, so much of their power as those of France. Hence the greater vassals did not acquire such complete independence; but when, after the eleventh century, the elective character of the empire was more fully recognised, the imperial power decayed; and that of the vassals rose during the period in which the contrary progress was taking place in France. And as the inferior barons had not been depressed, as in the latter country, by the overgrown power of the superior, Germany presented the example of a country in which the feudal system was carried out more completely, and for a greater length of time, than in any other; nor is there any in which the frame of society, to the present day, shows so many relics of its long predominance.

In Italy the feudal system, under the Carolingian government, was widely prevalent. The chief cause which in that country weakened and brought it to decay, or rather prevented its complete establishment, was to be found in the power and independence of the large towns, which at first effectually resisted, and afterwards broke down, the strength of the nobility.

In Spain, feudal tenures were of late introduction, and were very partially known, except in the kingdom of Arragon.

In the northern and eastern kingdoms of Europe (Sweden, Denmark, Hungary, Bohemia) they were never introduced at all, except in some few instances, and in these wholly without general effect.

(named after Louis Feuillée, a traveller in Chili). Climbing tropical American *Cuscutaceae*, one of which, *F. cordifolia*, is the Sequa or Cacaoon antidote of Jamaica, regarded

The seeds of an allied species, called *Abilla* in Peru, contain so much oil that the natives

FEVER

make rude candles by cutting cubical pieces of the seeds and stringing them on a thin stick, the point of which is

Feuillans. In Ecclesiastical History, a religious order, an offshoot from that of the Bernardines, established A.D. 1577, at the convent of Feuillant in Languedoc. The *Club des Feuillans* in the French Revolution was composed of moderates who receded from the Jacobins in 1791, and held their meetings in the convent of this order; it was extinguished in 1793.

Fever (Lat. *febris*). A disease in which one of the most general symptoms is increased heat of the body. The temperature is often actually higher than it should be; and the sensations of heat, dryness, and even burning of the skin, are often excessive, independent of any proportional increase of thermometric heat. The subject of fever has given rise to endless medical discussions and theories; and the definitions of the disease, given by different writers, are not less varied than numerous. In fevers there is generally great constitutional derangement, unaccompanied by local or perceptible organic disease. Fevers generally begin with languor of body and mind; chilliness, amounting to shivering, though the skin often at the same time feels hot; the pulse is quicker than it should be; respiration hurried or laboured; pains are complained of in various parts, and especially about the head, back, and loins; the appetite falls off, or there is nausea and vomiting; the mouth is dry; the bowels generally irregular; and the urine small in quantity and deep in colour. These, which constitute the first stage of ordinary febrile symptoms, are succeeded by flushings, a quicker pulse, and by mental anxiety and wandering, which, under many aspects and modifications, constitute the second stage: they are succeeded by the third stage, in which the leading appearances are a cleaner tongue, a more natural pulse, a moist skin, calm mind, the urine becoming more copious in quantity, and depositing a sediment as it cools. The symptoms of fever generally undergo an increase every evening, which is called an *exacerbation*; and this fluctuation often takes place more than once in the twenty-four hours, the violence of the attacks increasing with their occurrence, and forming what is called a *continued fever*. After some days, a *crisis* takes place; that is, the symptoms either take a favourable or an unfavourable turn. If the exacerbation and remission of symptoms are well marked, and occur once or oftener in the day, the fever is called a *remittent*; if the fever leaves the patient after some hours' duration, and returns at stated intervals, it is called an *intermittent*. [AGUE.] Fevers are also variously denominated, according to the characteristic symptoms, as *inflammatory*, *typhoid* (sometimes called *gastric* or *intestinal fever*), *relapsing fever*, and *typhus* or *putrid*, *nervous fever*, &c., or according to cutaneous appearances connected with them, such as *scarlet fever* and *yellow fever*.

FIACRE

Fiacre. The French name for a hackney-coach, so called as having been introduced by Sauvage, who lived in the Hôtel S. Fiacre.

Fiara. A word of Gothic origin, signifying, in Scotland, the prices of grain for the current year in the different counties, fixed by the sheriffs respectively in the month of February, with the assistance of juries. The form of striking the fiara, says Mr. Bell, in his *Law Dictionary*, is prescribed by the Acts of Sederunt, Dec. 21, 1723, and July 29, 1728. A jury must be called, and evidence laid before them of the prices of the different grains raised in the county; and the prices fixed by the opinion of the jury, and sanctioned by the judge, are termed the *fiara* of that year in which they are struck, and regulate the prices of all grain stipulated to be sold at the fiara prices. The fiara prices also regulate the price in contracts concerning grain (the product of the county) to be delivered, and where no price has been otherwise agreed upon between the parties. This method of ascertaining the prices of grain, &c. in each county has greatly facilitated the introduction into Scotland of the practice of letting land for corn rents convertible at the prices of the day. A similar system has been long pursued in England in the returns of the highest prices at which wheat and malt are sold at Michaelmas and Lady-day. This custom dates from 1582, and was established by an Act of that year, which provided that a certain portion of reserved rents should be paid in corn, or at corn prices. The Act was passed, we are told, at the instance of Burleigh, who, seeing the gradual depreciation of money, determined to arrest the fall in the real value of reserved rents, especially those enjoyed by corporations, by the stipulations mentioned above, wheat and malt being taken as sufficiently indicating corn values. It is from these sources that information as to prices of corn in successive years has been derived continuously since the date of the statute. The Oxford and Windsor prices have been published by Mr. Lloyd, sometime Professor of Political Economy in Oxford, and there is no doubt that similar records may be discovered in the archives of such corporations as the colleges in Cambridge and ecclesiastical chapters throughout England.

Fiat (Lat. *let it be done*). In Law, a short order or warrant of some judge for making out certain processes, &c.

Fibre (Lat. *fibra*). In Botany, one of the two bases of all vegetable structures. It may be compared in fineness to a hair, its diameter often not exceeding $\frac{1}{1000}$ of an inch. The finer divisions of roots are also denoted by this term.

Fibrille. In Botany, the minute subdivisions of the root, each being a small bundle of annular ducts, or sometimes of spiral vessels encased in woody tissue covered by cellular integument, and in direct communication with the vascular system of the root. The apex is composed of lax cellular tissue.

FICUS

Fibris. A term applied to the muscular fibre when cleansed by washing from all adhering impurities; or to the coagulum of the blood when the whole of the serum and colouring matter is washed out of it. It is whitish, insipid, and inodorous, and contains about 20 per cent. of nitrogen, nearly 2 per cent. of sulphur, and a trace of phosphorus.

The term *vegetable fibrin* has been applied to a modification of *gluten*.

Fibrolite. A mineral, analogous to Kyanite, of a fibrous texture, accompanying *corundum*, from the Carnatic and from China.

Fibula (Lat. *that which serves to fasten*). A long slender bone of the leg, placed upon the outer side of the tibia, the lower end of which forms the external ankle.

Fichtelite. A white crystalline substance found in a peat moss in Bavaria: it is a hydrocarbon = $C_{20}H_{10}$, isomeric with oil of turpentine.

Ficoides. A natural order of shrubby or herbaceous perigynous Exogens, inhabiting hot sandy plains. They are related to *Crasulaceae*, *Chenopodiaceae*, and *Silenaceae*, and especially to *Cactaceae*; but are distinguished by their embryo being curved round mealy albumen, their superior calyx, and their perigynous stamens. The succulent leaves of some are eaten. The order is sometimes called *Mæmbyraceae*.

Fiction of Law. This term has been defined, by writers on the civil jurisprudence, to be an assumption of the law that a thing is true which is either not true or which is as probably false as true. The utility of such fictions was merely, by substituting the imaginary for the true state of the case, to pass more rapidly over those parts of the subject which were not disputed, and arrive at the points really in issue. The most notorious instances (the proceedings in ejectment, and for barring estates tail) are now, however, abolished.

Ficus (Lat.). The Fig is the fruit of *Ficus Carica*, a small tree with broad lobed leaves, inhabiting the south of Europe and Asia. This fruit is not of the same nature as the apple, the orange, and other fleshy seed-vessels, but is a hollow receptacle, containing a great multitude of minute flowers, the ripe fruit of which is the seed (as it is wrongly called) that is embedded in the pulp. It is remarkable that the fig-tree, though it produces so agreeable a fruit, is in some measure poisonous, its milky juice being acrid and of the same nature as that of certain Indian species called *F. toxicaria*, *demonum*, &c., from their venomous qualities. The genus itself is of considerable extent, and its species are among the most noble objects belonging to the vegetable kingdom in tropical countries, where they often yield caoutchouc of the finest quality. *F. elastica* is particularly valuable for this purpose. The Banyan-tree, *F. indica*, belongs to this genus. [BANYAN.] The Pippal, or Sacred Fig of India, remarkable for its heart-shaped leaves with a long tail-like point, is *F. religiosa*.

FID

Fid. A short bar of wood or iron put through the heel or lower part of a topmast, and resting by its ends on the trestle-trees, on which the mast is therefore supported. When the topmast is to be lowered, it is first lifted to take the pressure off the fid, which is then withdrawn.

Fid or Splicing Fid. A sharp cone of wood or iron for opening the strands of rope.

Fide Jussor. In the Civil Law, one who engages himself for the debt of another, promising to pay in case the original debtor should make default: he is called in the law of England a *guarantor*.

Fidei Commissum (Lat. *committed or intrusted to faith*). A species of testamentary disposition recognised by the Roman law, by which a testator, in indirect terms, charged his heir to deliver over to a specified person the whole or a part of the goods which he inherited. Fidei commissa were usually adopted as a means of bequeathing property to persons legally incapable of directly receiving the bequest. Fidei commissa were, as their name implies, at first dependant entirely on the faith of the heir for their execution; but their execution was rendered compulsory by Augustus in some cases; and this became afterwards the general law, the heir being, however, entitled, where he voluntarily accepted the testament and charged himself with its execution, to retain one-fourth of the property intrusted to him for delivery.

Fidei Defensor. [DEFENDER OF THE FAITH.]

Fief (Lat. *feodum*). The French name for an estate in lands held of a feudal superior. In English Law language, a *fee*: also termed a *fynd* by writers on feudal jurisprudence. [FEUDAL SYSTEM.]

Field (Ger. *feld*; Dutch, *veld*). In Agriculture, a portion of land enclosed by a fence, or rendered distinct by some line of separation, so as to adapt it for culture. In former times, and until within the last two centuries, almost all the land cultivated with the plough throughout Europe was unenclosed; and the term *field* was then applied, in Britain at least, to the lands under culture by the plough. Subsequently, when farmers enclosed and subdivided a portion of the lands near the farmyard, these portions were called *fields*, the more distant portion which remained open being called *open field*, or *common field*; while grass lands unenclosed were called *commons*. In the present improved state of agriculture, every farm is divided into fields, either simply by lines of demarcation, which are sufficient when no animals are to be grazed on the farm; or by lines of separation which will act as fences, such as walls, hedges, ditches, &c., where cattle are to be grazed. Without some regular fixed division of arable lands, it would be next to impossible to conduct a rotation or succession of crops. It is interesting to observe that as agriculture in a rude state had no fences, so this is also beginning to be the case in agriculture in its most

FIELDVOLE

refined form; because it is found much more advantageous, for the production both of butcher's meat and manure, to consume the grass and herbage grown on farm lands in farmyards, with the single exception of that portion which is eaten by sheep; and these are confined to successive portions of grass land by light nets or hurdles, scarcely visible at a short distance. By thus getting rid of fences of every description, from a tenth to a twentieth will be added to the contents of the greater number of corn farms; and a very considerable first cost and annual expense will be saved in planting hedges or building walls, and in keeping them in repair afterwards.

FIELD. In Heraldry, the tincture, or combination of tinctures, which forms the ground of the escutcheon on which the device or charge is delineated. [TINCTURE.]

Field Lark. [LARK.]

Field, Magnetic. The space near the poles of a magnet through which the magnetic force is capable of exerting a perceptible influence.

Field Marshal. The highest military title in this and some other countries. The term is derived from the *maréchal de camp* in the old French service, and was long in use among the Germans in its present acceptation before it was adopted in this country.

Field Sketching. For Military purposes, the art of depicting in plan, quickly and faithfully, the natural features of a country, so as to give to an experienced observer the best possible idea of its character.

Field of View. In a telescope or microscope, the space within which objects are visible when the instrument is adjusted to focus.

Fieldfare. A bird of the Thrush tribe (*Turdus pilaris*, Linn.) which is a seasonal visitant in this island. It makes its appearance about the beginning of October, migrating from the colder northern parts of the Continent in flocks, numerous according to the severity of the season. They fly in a body; and if alarmed when dispersed over a field in quest of food, they collect together as they fly off, and often settle in a swarm on the same tree. They leave us about the latter end of February, or the beginning of March; and retire to breed in Sweden, Norway, Russia, and the northern parts of Asia as far as Kamtschatka.

Fieldvole. A name of the short-tailed field-mouse or meadow-mouse (*Arvicola agrestis*, Cuv.). Fieldvoles subsist exclusively on vegetable productions; and being, like the rest of the rat tribe, extremely prolific, multiply occasionally to such a degree, even in this country, as to become the most injurious of our wild quadrupeds. 'After having followed the labours of the reaper, and taken their share of the harvest, the fieldvoles (says Mr. Bell) attack the newly sown fields, burrowing beneath the surface, and robbing the husbandman of his next year's crop; and at length, retreating to the woods and plantations, commit such devastations on the young trees as would scarcely be

FIERI FACIAS

credible, were not the evidence too certain to be doubted. In the years 1813 and 1814 these ravagers were so great in the New Forest and the Forest of Dean, as to create considerable alarm lest the whole of the young trees in those extensive woods should be destroyed by them. A timely attention to restraining their increase by the aid of terriers, ferrets, and traps, is imperative on those who have the charge of young plantations; but when the numbers of the fieldvole have surpassed the usual bounds, then it is recommended to dig holes about a foot in depth and the same in diameter, taking care to make them much wider at the bottom than at the top, so that the animal when once in cannot easily get out again. In holes of this kind Mr. Jesse states that at least thirty thousand fieldvoles were caught, in the course of three or four months, in Dean Forest plantations; that number having been counted out and paid for by the proper officers of the forest.

Fieri Facias (Lat. *cause it to be done*). In Law, a judicial writ, which lies where judgment is had for debt or damages recovered in the king's courts; by which writ the sheriff is commanded to levy the debt and damages on the goods and chattels of the defendant. Under it may be taken all personal goods and chattels, except wearing apparel to the value of five pounds; money and bank-notes; leases and terms for years. As to growing crops, see 14 & 15 Vict. c. 25.

Flûte (Ger. *pfeife*). A small musical wind instrument of the flute species played by holes, shrill in tone, and rarely used except in military bands.

Fifteenth. In Music, an interval of two octaves; also a name given to a stop on the organ, a double octave above the diapason, as its name imports.

Fifth. In Music, one of the harmonical intervals or concords. It is the second in order of the concords, the ratio of the vibrations of the notes that afford it being as 2:3. It is called the *fifth*, because in the natural or diatonic scale of music it comes in the fifth place or order from the fundamental. The ancients called it *diapente*, and the Italians at present call it *quinta*. The *imperfect, defective, or false fifth*, called by the ancients *semi-diapente*, is less than the perfect fifth by a lesser semitone.

Fifth-monarchy Men. A fanatical sect, who formed a principal support of Cromwell during the Protectorate. They considered his assumption of power as an earnest of the foundation of the fifth monarchy, which should succeed to the Assyrian, the Persian, the Grecian, and the Roman, and in which Jesus Christ should reign with the saints on earth for the space of a thousand years. Upon the restoration of the royal family, and the return of the kingdom to its former principles in church and state, a party of these enthusiasts, headed by a man of the name of Venner, made a desperate insurrection in the streets of London, which was put down with the slaughter of a great number of them.

FIGURATE NUMBERS

Fig. [FIGURA.]

Figurate Counterpoint. In Music, that which contains a mixture of discords together with the concords.

Figurate Numbers. In Arithmetic, a series of numbers derived from an ordinary arithmetical progression by a certain uniform law. They may be best defined by premising that an arithmetical series whose first term is 1 and common difference d , constitutes a series of *figurate numbers of the first order* and d^{th} class, and that the general or n^{th} term of a series of figurate numbers of the m^{th} order is the sum of the first n terms of the series of figurate numbers of the next lower or $(m-1)^{\text{th}}$ order. Thus for the figurate numbers of the first four orders and of the d^{th} class, we have—

$$\begin{aligned} \text{I} & 1, 1+d, 1+2d, 1+3d, \dots, 1+(n-1)d, \\ \text{II} & 1, 2+d, 3+2d, 4+3d, \dots, \frac{n}{1} \left(1 + \frac{n-1}{2}d\right), \\ \text{III} & 1, 3+d, 6+4d, 10+6d, \dots, \frac{n(n+1)}{1.2} \left(1 + \frac{n-1}{3}d\right), \\ \text{IV} & 1, 4+d, 10+3d, 20+6d, \dots, \frac{n(n+1)(n+2)}{1.2.3} \left(1 + \frac{n-1}{4}d\right) \end{aligned}$$

The general law is evident; in fact, if we represent by the symbol (m, d) , the n^{th} figurate number of the m^{th} order and d^{th} class, or, what is the same thing, the sum of the first n figurate numbers of the $(m-1)^{\text{th}}$ order and d^{th} class, we have—

$$(m, d)_n = \frac{n(n+1) \dots (n+m-2)}{1.2 \dots (m-1)} \left(1 + \frac{n-1}{m}d\right).$$

The figurate numbers of the second order and d^{th} class give rise to what are called *polygonal numbers* of the d^{th} order, which receive the special names of *triangular, quadrangular, &c.* . . . $(d+2)$ -gonal, according as d has the values 1, 2, &c. . . . The origin of this nomenclature is traceable to the fact that a polygonal number of points may always be arranged so as to form and fill a regular polygon in a symmetrical manner. To illustrate this, take the pentagonal numbers 1, 5, 12, 22 . . . , corresponding to $m=2$ and $d=3$. Starting with the regular pentagon 1, 2, 3, 4, 5, and fixing upon any corner, produce its two sides 1, 2 and 1, 5, and its two diagonals 1, 3 and 1, 4, until their whole lengths are doubled; in this manner a second regular pentagon 1, 6, 8, 10, 12 will be obtained whose sides are respectively double those of the original. Midway between the points 6, 8, 10, 12, insert three $(d-2-d)$ new points 7, 9, 11, so that the points on the contour of the new pentagon may be at the same distance asunder as before. By elongating the sides and diagonals of the second pentagon to the same extent as before, and inserting two new points into each of the three sides opposite 1, a third pentagon of a similar nature will be obtained. Now the points forming the contours of the several pentagons will clearly correspond to an

FIGURE

arithmetical progression whose common difference is $d = 5 - 2 = 3$, and the points upon and within the several pentagons will correspond to the pentagonal numbers obtained by the successive summation of the terms of this arithmetic series.

In a similar manner the figurate numbers of the third order and d^{th} class lead to *pyramidal numbers* of the d^{th} order, which receive the distinctive names of *triangular*, *quadrangular* . . . $(d + 2)$ -gonal as before. It is manifest, in fact, that a pentagonal pyramid could be formed by superposing, in a symmetrical manner, layers of pentagons of the kind just described; and according as such a pyramid consisted of 1, 2, 3, 4 . . . layers, it would enclose 1, 5, 18, 40 . . . points.

Figurate numbers of a higher order than the third of course transcend geometrical representation.

Figure (Lat. *figura*, *a shape*). In Geometry, a space bounded by lines or by planes. The term *figure*, when synonymous with *diagram*, denotes the representation (on paper for example) of the object of a theorem or problem.

All bodies are necessarily enclosed by one or more boundaries, and therefore possess figure; hence *figurability* is reckoned one of the essential properties of matter.

In Arithmetic, the numeral characters, or ten digits, by which numbers are expressed, are also termed *figures*. They are supposed to be of Indian origin, and to have been introduced into Europe by the Moors of Spain in the thirteenth century; but the date of their introduction is much disputed. [ARITHMETIC.]

FIGURE. In Logic, this word is applied to the form of a syllogism with regard to the disposition of the middle term. [LOGIC.]

FIGURE. In Rhetoric, a mode of speech in which words are changed from their literal and primitive sense. It is almost impossible to give, within the limits of a definition, the meanings of which this term is susceptible; but under the separate heads, such as ANTI-THESIS, METAPHOR, &c., will be found a notice of the different figures used in composition.

Figure of Merit. In rifle-shooting at a target, the number denoting the individual success of any rifle.

Figure-head. The figure, statue, or bust, representing the subject of the ship's name, on the projecting part of the prow, above the cut-water.

Filacer or **Filazer** (Fr. *fil*, *thread*). An officer of the Court of Common Pleas, who filed writs. The filacers (of whom there were fourteen) are mentioned as early as the stat. 10 Hen. IV. The office (with other like offices) was abolished by 1 Vict. c. 30.

Filaria (Lat. *filum*, *a thread*). A genus of *Entozoa*, which has been found under the skin of man in the cellular tissue, especially in the legs, sometimes attaining the length of ten feet, and causing great pain. It is found in the hot countries of both the Old and New Worlds.

FILICES

Filbert or **Filberd**. The well-known fruit of one of the varieties of the cultivated nut, *Corylus Avellana*. It is a seed-vessel enclosed within an involucre or cupule, which is commonly called the *husk*. This organ is of the same nature as the cup of the oak and the prickly case in which the nuts of the sweet chestnut and the mast of the beech are enclosed. In the filbert it is much larger than in the common nut; and this character, together with its lengthened figure, distinguishes the two races of nuts and filberts, each of which has many varieties. The best known varieties of the filbert are the red, the frizzled, and the white, the latter being most commonly grown in this country.

File (Ger. *feile*). An instrument for abrasion, consisting of a piece of steel, cut with a series of regular notches, so as to take hold of the surface, and remove the asperities. Files are known by the names of *round*, *half-round*, *triangular*, and *flat* files, which are applied to the various forms required to be produced; their temper and degree of fineness depends on the materials on which they are intended to act, and the degree of finish which they are required to produce.

FILE (Lat. *filum*, *a thread or line*). The Military term for two soldiers, front and rear rank men. Thus, a company of twenty-five files contains fifty men.

File Marching. The marching of a line two deep, when faced to the right or left, so that the front and rear rank march side by side.

Filfish (*Balistes*). A genus of Acanthopterygious fishes, in which the anterior dorsal spine is deeply serrated, and the skin excessively rough and shagreened.

Filibusters. This word is commonly used in America as a name for piratical adventurers of any nation. It is an Anglicised form of the French *filibustier*; but the latter is nothing more than a corruption of the English *freebooter*.

Filices (Lat. pl. of *fili*, *a fern*). One of the principal groups of *Acrogens*. They are commonly called *Ferns*, and consist of arborescent or herbaceous perennials, very rarely annual plants. Those of arborescent habit have a trunk varying from two or three to sixty or more feet in height, formed of the consolidated bases of the fronds, surrounding a soft central mass of tissue. Those of herbaceous habit either have a caudex formed on a plan similar to the trunk of the arborescent kinds, but on a smaller scale, the young fronds forming the growing point; or they have a more or less fleshy rhizome whose growing point is in advance of the development of the fronds, which are produced from its sides instead of its apex.

Ferns may be recognised by the circinate growth of their young leaves, and by their hypophyllous fructification. The fronds vary much in size and form; but, in the majority of instances, there is no material difference of aspect between those which are fertile and

FILICIC ACID

those which are sterile. In some few, however, including the whole group of *Acrostichæ*, there is a manifest contraction of the fertile fronds, which are sometimes reduced to mere ribs, clustering with spore-cases.

The spore-cases, which are collected into heaps called *sori*, consist of little one-celled vesicles, girt either longitudinally, vertically, or obliquely by a jointed ring, which nearly, or in some cases completely, surrounds them. This ring is elastic, and by its contraction disrupts the spore-case and scatters the contained dust-like spores. The sorus, or heap of spore-cases, is in some groups entirely naked, but in others is covered while young by a membrane called the *indusium*.

The spores are produced by cell-division within the spore-cases, and are consequently unattached, and variously shaped and sculptured. They consist of two coats containing a grumous mass. On germination the outer coat bursts, and the inner is elongated and protruded, and by cell-division becomes converted into a thin marchantiform frond or prothallus. On the under surface of the prothallus two kinds of bodies are borne, one of which, the antheridium, produces spiral ciliated spermatozooids; the other, forming the archegonium or female cell, being sunk in the tissue. The cell at the base of the archegonium, after impregnation, gives rise to a new plant, which is gradually developed, and is of different duration in different species, producing successive crops of spore-cases without further impregnation if the species is perennial.

Many schemes have been proposed for the classification of ferns, but that seems to be preferable which is based on the modifications of the vascular system taken in conjunction with the fructification. All ferns may be referred to one of the groups *Ophioglossaceæ*, *Marattiaceæ*, or *Polypodiaceæ*. The two former have the spore-cases ringless, and are distinguished by the first having the fructifications marginal on rachiform fronds, and the second having them dorsal on flat leafy fronds. The *Polypodiaceæ* are known by their spore-cases having a jointed ring. This group comprises much the larger portion of the order, and is divided into several minor groups. The *Ophioglossaceæ* are called *pseudo-ferns*, as they want the character of circinate venation present in all true ferns.

Filicic Acid. An acid obtained from fern root: it is a fatty matter, soluble in ether and in alkalies.

Filiform (Lat. *filum*, a thread). In Zoology, when a part is slender, thread-shaped, and of equal thickness.

Filigraïne, Filigree or Filagree (Ital. *filigrano*). A fine ornamental work of flowers, fruit, &c. formed with gold or silver wire. It is an Eastern invention, much cultivated in those provinces of Italy which have maintained an intercourse with the Levant.

FILL. The Sea term for bracing a yard which had been laid aback, so that the wind may act on the after or proper side of the sail.

FIN

(Fr. *filet*, a thread). In Architecture, a small square member placed above or below other larger members, in orders. The term is used by carpenters and joiners to express a small piece of wood to which boards, joists, or quarters are nailed.

Filose (Lat. *filum*). In Zoology, when a part ends in a thread-like process.

Filtration. The process by which liquids are separated from substances mechanically suspended in them; it is also sometimes used to separate colouring matters and other bodies which are in a state of solution, and which are removed by the substance or matter through which the liquids are filtered. Unsized paper is commonly used in the chemical laboratory for the former purpose, and is known under the name of *filtering paper*. In the arts, linen or woollen calico bags of different forms are frequently employed, containing charcoal or other materials, through which the liquids requiring purification are suffered to trickle slowly. In water filters, the coarser particles are generally collected in a piece of sponge, and the further separation of the more finely divided matters or organic taints is effected by layers of sand of various degrees of fineness mixed with a proper quantity of charcoal. (See Faraday's *Chemical Manipulation*; and Ure's *Dictionary of Arts, &c.*) The filter-beds of the London water companies are similar arrangements upon a proportionate scale.

Fimbriæ (Lat. *fringe*). In Anatomy, the jagged processes of the abdominal opening of the oviduct, or *Fallopian tube*, are so called.

Fin (A.-Sax. *finna*). A flattened expanded organ, projecting from the body, and serving as an instrument of locomotion in water.

Many species of the whale tribe possess an immovable fin upon the back, composed merely of a reflection of integument over a mass of dense and ligamentous cellular membrane; the tail fin in the same order has a similar structure, but is moved by the action of the muscles the caudal vertebrae, which are continued through the middle part. The anterior fins, corresponding to the pectorals in fish, are susceptible of greater variety of motion, from being supported by a series of bones corresponding to those of the fore extremity of other mammals. In fishes the fins are supported by elongated filamentary bones or rays, the nature and number of which afford the zoologist important characters for distinguishing the different groups; and in works of Ichthyology a system of notation is employed, which briefly but clearly expresses these characters. Thus the formula of the number of fin-rays in the perch is thus expressed:—

d. 16, 1 + 13; *p.* 14; *v.* 1 + 5; *a.* 2 + 8; *c.* 17,

which signifies that *d.*, the dorsal fin, has in the first fin 16 rays, all spinous or bony; in the second fin, 1 spinous plus 13 that are soft. *p.*, pectoral fin, 14 rays, all soft. *v.*, the ventral fin, with 1 spinous ray plus 5 that are soft. *a.*, the aural fin, with 2 spinous rays plus 8 that

FINAL

are soft. *c.*, the tail or caudal fin, 17 rays. In enumerating the rays, those only which extend from the longest ray in the upper portion to the longest ray in the lower portion, both inclusive, are counted.

Final or Remaining Velocity of a Projectile. Its velocity at the end of any given range.

Finale (Ital.). In Music, the last of a series of movements in a composition; also the closing scene of each act of an opera.

Finance (Low Lat. *financia*). This word in English phraseology is generally limited to systems of taxation, and especially to the schemes by which governments attempt to secure the funds necessary for the administration of public affairs, and particularly by loans. Hence, as all taxation must be paid, as a rule, out of profits, and it is from profits only that capital is replaced and augmented, financial expedients are of great interest to economists, because an erroneous or mischievous system of finance may seriously impair the productive energies of a people, and induce that state in which the accumulation of capital ceases.

Up to comparatively late times, finance was never treated as a subject on which economical considerations are of paramount importance. Money was needed for public purposes, and financiers merely considered how it could be procured in the manner easiest to themselves, and not in the manner easiest to the nation. Hence laws were enacted which seriously affected the industrial powers of the community. For instance, during the greater part of the eighteenth century (according to Macpherson), the cost of collecting the customs revenue in Scotland exceeded the proceeds of taxes, and money had to be remitted from England in order to meet the charges incurred in procuring the revenue from the Scotch ports. Of course such a system was simple waste.

Of late years the principles of finance have been far better understood in this country, and taxation has been based upon a rational theory. But other communities are far in the rear of any sound doctrine on these subjects. Few countries, perhaps, were so ill-situated as England before the time in which the question was first agitated, and, with the exception of some details, practically settled. To this, probably, we may attribute the completeness of the reaction. But the financial schemes of the continental governments generally, and of the United States in particular, are a mass of irrational confusion and mischievous error. [TAXATION; NATIONAL DEBT.]

Fine. [FRINGILLIDÆ.]

Fine. In Law, as a punishment, is a pecuniary mulct or amende imposed by a competent jurisdiction. The party thus mulcted for offences against a feudal superior was said, in the language of that jurisprudence, '*finem facere de transgressionibus cum rege, domino, &c.*, to make an end of his offence: whence the word *fine*. Fines are in no case determined as to amount by common law, and seldom by sta-

FIR TIMBER

tute, except as to their maximum; but by the general cautions of Magna Charta and the Bill of Rights, excessive fines ought not to be imposed. Courts of record have in general the power of imposing fines in case of contempt, and also on conviction of offences punishable in this manner. The mode of returning, estimating (i.e. entering on the rolls of a court), and levying fines is now regulated by 3 & 4 Wm. IV. c. 99, and 22 & 23 Vict. c. 21.

Fine of Lands. In Law, a species of fictitious conveyance or record for the settling and securing lands and tenements, now by stat. 3 & 4 Wm. IV. c. 74 rendered obsolete. [FEN TAIL.]

Fine Stuff. In Architecture, the preparation used in common ceilings and walls for the reception of paper or colour. It is composed of lime, slaked and sifted through a fine sieve, then mixed with a due proportion of hair and sand; the lime is a rich fat lime, and the sand is very fine. A coarser kind of material, used for the first or the rendering coat and for the floating coat, is called *coarse stuff*.

Fineering. [VENNER.]

Fingal's Cave. [BAALIT.]

Finger-board. In Music, the black board attached to the neck of instruments of the viol class, on which the strings are pressed by the fingers for the purpose of adjusting their lengths so as to produce the different sounds.

Fingering. In Music, the art of arranging the fingers on instruments of all classes, so that they may be in the best positions for performing the different passages written for such instruments.

Finial (Lat. *finis*, an end). In Gothic Architecture, the top, or finishing, of a pinnacle, or gable, as it is now generally understood; but in ancient documents, an entire pinnacle is understood by this term. [CROCIATA.]

Finishing Coat. In Building, the last coat of stucco when three coats are used. When in the third coat fine stuff is used for affording a hold to the paper, it is called the *setting coat*.

Fjord. The Norwegian form of the word *frith* or *firth*, denoting those arms of the sea which penetrate deep into the land.

Fiorite. A silicious incrustation, from *Fiora* in Iechia.

Fir (A.-Sax. *furh*). A general name for various coniferous trees, but particularly applied to the species of *Abies*, some of which, occasionally separated under the name of *Picea*, are called Silver Firs. The name of Spruce Fir is given to the species of *Abies* proper, and particularly to *Abies excelsa*. The Firs are mostly valuable for their timber, which forms some of the varieties of Deal.

The word *fir* is identical with the Latin *quercus*. (Max Müller, *Lectures on Language*, second series, p. 222.)

Fir Timber. The wood obtained from any species of the genera *Pinus* and *Abies* is called by builders *fir*; though at the present day the tendency of the technical authorities is to limit the word to the wood proceeding from the ports

FIRE

of Northern Europe: the American timber being known as *pine*; that from Vancouver's Island, as *masting timber*; and from New Zealand as the *cowrie wood*. There are different qualities in the fir brought to market, which are usually confounded by the London architects. The Baltic fir, which is obtained from the genus *Pinus*, is usually met with in scantlings of fourteen inches square; the Swedish, obtained from the same genus, is about ten or twelve inches square; and the Norway fir, eight inches to ten inches square, obtained from the *Abies*, is of very inferior quality.

Fire (Gr. *wp*, Ger. *feuer*). [FLAME and HEAT.]

Fire of Artillery, or of other troops, is defined according to its direction as regards the line of works or troops fired at; *direct* when perpendicular to the front of the line, *oblique* when forming an angle with the front, *enfilade* when raking the length, *slant* when at a small, and *reverses* when at a large angle with the rear of the line. *Plunging* fire is that directed down from a height; *ricochet* is rebounding of the shot; *vertical* fire is throwing the shot high into the air, whence it falls among the enemy.

Fire Balls (called also *Bolides* and *Fiery Meteors*). In Meteorology, luminous bodies which suddenly appear in the sky, usually at a great height above the earth; they shoot through the heavens with immense velocity, and are sometimes accompanied with the fall of an *aërolite*. These meteors are of frequent occurrence; and are believed to be portions of matter composing several rings in the interplanetary spaces, through which the earth passes in its orbit. They pass with immense velocity through our atmosphere, and the consequent retardation of their motion develops so much heat as to dissipate them in most cases in vapour. Sometimes, however, from the greater size of the masses, or from their more vertical descent, they reach the earth in an intensely heated condition. [METEOR, LUMINOUS.]

Fire Blast. A term of very doubtful meaning, like the word *Night*. In Agriculture, it is sometimes applied to plants which are suffering from the mildew fungi or from minute insects; but it is properly applicable only when the delicate parts of plants are too suddenly exposed to a brilliant sun, and the rapid transpiration which takes place in consequence dries up and shrivels their leaves.

Fire Brick. A brick used for the purpose of lining fireplaces, furnaces, &c., which, from the nature of the clay of which it is made, is capable of withstanding a great degree of heat. The clay should be a nearly pure silicate of alumina, and free from lime. Stourbridge clay, which is in great request for the manufacture of fire bricks, contains from 60 to 70 per cent. of silica, and from 20 to 30 alumina, with traces only of oxide of iron and carbonate of lime. Some of the Monmouth and Newcastle clays are similarly constituted, and resist high temperatures without a tendency to fusion. [CLAY.]

FIRE ENGINE

Damp. The explosive mixture of light carburetted hydrogen and air found in coal mines. [CARBURETTED HYDROGEN.] It is also generated in marshes, bogs, and stagnant pools.

Fire Engine. This most useful machine is constructed in a variety of forms, all of which, however, agree in one principle. It generally consists of a double forcing pump communicating with the same air-vessel; and instead of a force-pipe a flexible leathern hose is used, through which the water is driven by the pressure of the condensed air in the air-vessel. The annexed diagram represents a section of the apparatus in Newsham's engine. The pipe T descends into a receiver or vessel containing a supply of water. This pipe communicates with two suction valves V, which open into the pump barrels of two forcing pumps A, B, in which solid pistons P are placed. The piston rods of these are connected with a working beam F, elongated so that a number of persons may work at both ends of it at once. Force pipes *z, z* proceed from the sides of the pump barrel above the valves V, and they communicate with an air-vessel M, by means of forcing valves V, which also open upwards. The pipe descends into the air-vessel near the bottom. This pipe is connected with the flexible leathern hose L, the length of which is adapted to the purposes to which the machine is to be applied. The extremity of the hose may be carried in any direction, and may be introduced through the doors and windows of buildings. By the alternate action of the pistons, water is drawn through the suction valve, and propelled through the forcing valves, until the air in the top of the vessel M is highly compressed. The pressure acts on the surface of the water in the vessel, and forces it through the leathern hose in continued stream, so as to spout from its extremity with a force depending partly on the degree of condensation, and partly on the elevation of the end of the hose above the level of the engine. It is to be considered that the pressure of the condensed air has, in the first instance, to support a column of water, the height of which is equal to the level of the end of the tube above the level of the water in the air-vessel; and until the pressure exceeds what is necessary for this purpose, no water can spout from the end of the hose; and, consequently, the force with which it will so spout will be proportional to the excess of the pressure of the condensed air above the weight of the column of water, whose height is equal to the elevation of the end of the hose above the level of the water in the air-vessel. (*Cabinet Cyclopædia*, 'Hydrostatics and Pneumatics,' p. 326.)

The fire engine has received various improvements from Bramah, Dickenson, Simpkin, Raventree, Philips, and others. The first steam fire engines made in London were by

FIRE ESCAPE

Mr. Braithwaite in 1830. One or two were worked publicly at fires, and were afterwards sold to continental governments. Some years afterwards they began to be generally used in North America, and in London was revived when the London fire brigade had a powerful floating steam fire engine constructed for use on the river Thames. This engine was designed and constructed by Messrs. Shand, Mason and Co., who in 1868 made the first land steam fire engine which had been constructed since those of Braithwaite. This engine was sent to St. Petersburg for the Russian government; a second engine was made and used experimentally by the London fire brigade during the year 1860, the result of which was very successful. At the Exhibition of 1862 there was a competition of steam fire engines: see Jurors' Report, International Exhibition, 1862, 'Appendix to Class 8, Special Jury for Fire Engines, where full particulars are given of the details of the engine.

Fire Escape. Any machine or apparatus for the purpose of enabling persons to escape from the upper storeys of houses on fire. The many contrivances which have been proposed for accomplishing this desirable object are of two kinds; the first kind comprising those by means of which the escape is effected without external aid, and the second those requiring the assistance of persons without. Of the first kind the most obvious is a rope ladder, which may be kept in a sleeping apartment, and used, when needed, by fastening one end of it to a window-sill or bedpost. But unfortunately contrivances of this kind can rarely be of any use; for supposing them hand when the alarm of danger is given, few persons can command the coolness and attention which are requisite for fixing and adjusting the apparatus; and even then it is only the strong and active who could safely descend by such means from a considerable height.

In escapes of the second kind, the object is to enable persons without to establish speedily a communication with an upper room, so as to afford the inmates the means of safe descent; or to remove them if necessary, as in the case of the feeble or children. Mr. Braby's fire escape, described in the thirty-fourth volume of the *Transactions of the Society of Arts*, consists of a car or cradle, which is made to slide on a slip of plank fixed to a pole, and is governed by a rope. Mr. Ford's escape consists of a spar of timber about thirty-five or forty feet long, having two projecting arms at the top furnished with prongs, by which a firm bearing against the wall of a house is obtained. A grooved pulley is mortised into the spar near the top, and another near the bottom; over the pulleys runs an endless rope, to which is attached at one point a main rope, and at another the semi-circular brace of a large grooved roller, which traverses up and down the space between the pulleys. This brace carries on the under side of the spar a hook, to which a cradle is attached

FIRE, ST. ANTHONY'S

by which persons can be easily lowered to the ground.

In the year 1819, Mr. J. Gregory patented a fire-escape ladder consisting of sliding ladders placed upon a movable carriage, and capable of being extended by the successive drawing out of the separate parts. This apparatus is described and illustrated in the *Mechanic's Magazine*, No. 296. In the year 1840, Messrs. Harvey and Braidwood recommended for use in the city of London a fire escape which was founded upon Gregory's invention, and which contained some valuable additions and improvements designed by Mr. Wivell. Mr. Wivell's fire escape is described in the *Mechanic's Magazine*, No. 723. The principal feature in the modern apparatus consists in the addition of a long canvas trough, extending the whole length of the main ladder, and intended not only to facilitate the descent of weak and timid people, but also to protect them from the heat of any issuing flames; and so necessary is some safeguard of this kind, that it is essential to protect the canvas trough itself by a metal screen.

The escape now in use consists of a main ladder about twenty-four feet long, provided with a canvas trough, and capable of extension to a greater length, either by sliding out additional pieces, or by folding back a light ladder which is hinged upon a joint at one extremity of the main portion. It is balanced upon the axis of a pair of wheels, so that two men can move it promptly and readily from place to place, and it appears to be the most simple and effective of all the numerous contrivances which have hitherto been suggested.

For a description of various other contrivances of a similar kind, see the *Transactions of the Society of Arts* above quoted, and the *Mechanic's Magazine* for January and July 1863, and July 22, 1864.

Fire Fly. A name commonly given to those insects which have the singular property of emitting a luminous secretion. This power is not confined to insects of one organisation or order. Among the Coleoptera, the *Elater noctilucus* and the female glow-worm are conspicuous examples. The *Fulgorida*, or lantern and candle flies, are also described, but some think apocryphally, as luminous insects.

Fire, Greek. An incendiary composition which was discharged from tubes; a fact which has led many engineers to confound it with gunpowder, and these tubes with cannon. It was known in the east of Europe as early as the year A.D. 673, when, it is said, Callinicus, an architect of Heliopolis, taught the use of it to the Greeks. It did not reach the west of Europe till much later. A receipt for a composition may be found in the *Treatise of Marcus Græcusa*, and in a Spanish MS. of the thirteenth century, in the Bodleian Library.

Fire Lock. A term applied in the sixteenth century to the musket or pistol with a wheel lock, and later to that with a flint lock.

Fire Raising. [Anson.]

Fire, St. Anthony's.

FIRE WORSHIPPERS

Fire Worshippers. [GUERRAS.]

Fireship. A vessel filled with combustible materials for the purpose of being sent in burning state among the ships of an enemy, in order to set them on fire. As the destruction of the vessel itself is a necessary consequence, it must be abandoned by the men, and therefore cannot be steered after ignition has been effected. Hence fireships are formidable only to vessels which cannot be manœuvred, either by reason of their having been disabled, or on account of their occupying a confined space, as a harbour, where there is not room for escape.

Fireworks. [ПЯТОУСНУ.]

Firkin. A measure of capacity, being the fourth part of a barrel, or containing 9 ale gallons or $7\frac{1}{2}$ imperial gallons; that is, 2,538 cubic inches. The word is a diminutive of *four*, with which the terms *farthing* and *friot* may be compared.

Friot. Strictly, the *fourth* part of a boll of meal. A dry measure used in Scotland, but of different capacities according to the article it is used for measuring. The Linlithgow *wheat friot* is to the imperial bushel as 998 to 1; and the *barley friot* to the imperial bushel as 1456 to 1.

Firmament (Lat. *firmamentum*, a support or prop). In the language of the old astronomers, the orb of the fixed stars, or the most remote of all the celestial spheres. In common language it signifies the same thing as *heaven* or *sky*. [HEAVEN.]

Firman (more properly *Fermdn*). In the Persian language, this word signifies a command, and is applied in Turkey, Persia, and India to mandates or certificates of the sovereign, issued for various purposes. Those best known to Europeans are given to travellers, and serve as passports. The *fermdn* has at its head in Turkey the cipher of the reigning sultan, written in a complicated manner, affixed by the chief secretary of the sign manual.

First Coat. In Architecture, the *laying* the plaster on the laths, or the *rendering*, as it is called, on brick when only two coats are used. When three coats are used, it is called *pricking up* when upon laths, and *roughing in* when upon brick.

First Fruits (Annates or Primitiæ). The profits of every spiritual living for the first year after its avoidance, which the new incumbent paid in Catholic times to the pope, but since the Reformation to the king. The valuation is that which was made by Henry VIII. The statute 2 Anne transfers the first fruits and tenths of all livings over 50*l*. at that time to a fund called Queen Anne's Bounty, for the increase of the smaller benefices, those under 50*l*. being released from any payment of the kind.

Firth. [FARTZ.]

Fiscal (Lat. *fiscalis*, from *fiscus*, a purse). Anything relating to the pecuniary interest of the sovereign or the community.

Fischerite. One of the native hydrated phosphates of alumina, named after its discoverer, Fischer.

FISHERY

Fiscus (Lat.). [ÆRARIUM.]

Fish. In Architecture and Engineering, a piece of wood, or metal, secured to the side of another piece in order to strengthen it.

FISH. In Nautical phraseology, has two significations: first, it is an apparatus of blocks and ropes used in hauling up the flukes of an anchor towards the ship's bows, to prevent them from catching in passing objects; secondly, *fish-fronts* are curved pieces of timber bound along the outside of a broken spar, to give it firmness. *Side-fishes* are the convex timbers forming the rounded sides of a made mast.

FISH. In Zoology. [PISCES.]

Fish Davit. In Navigation, a piece of wood or iron for lifting the fluke of the anchor to the bill board.

Fishery. The fisheries of the British Islands are partly coast and river, and partly carried on in the open sea at a greater or less distance from the shore. Of the former, salmon, herring, pilchard, and oyster are most important; of the latter, cod, turbot, and whale. 1. The salmon fishery has considerably diminished in importance of late years. That of Scotland is regulated by 9 Geo. IV. c. 39 and subsequent Acts. 2. The herring fishery, at first almost engrossed by the Dutch, was fostered in 1749 by a tonnage bounty granted on vessels employed in it. Under this system the fishery does not appear to have thriven. The bounty was gradually withdrawn, and finally ceased in 1830. The most important seats of the herring fishery at the present day are the coasts of the north-east of Scotland. In 1834, 11,000 boats and 82,000 persons (fishermen and boys, coopers, curers, &c.) were employed in this fishery. 3. The pilchard fishery is carried on almost entirely on the coasts of Devon and Cornwall. 4. Oysters are found on most parts of our coast, but the principal seats of the trade of breeding them for the London market are Kent and Essex. 5. Turbot, cod, and mackerel are the principal articles of the fisheries off the British coasts. Turbot are chiefly caught by Dutch fishermen, close to the shores of Holland. In 1833 a report was made by a committee on the British Channel Fisheries, in which the declining state of those fisheries is much commented upon, and attributed to three causes: the extensive interference and aggression of the French fishermen on the coasts of Kent and Sussex; the large quantities of foreign-caught fish illegally imported and sold; and the great decrease and comparative scarcity of fish in the Channel; which last they attribute to the destruction of spawn. But by far the greatest fishery of cod, hake, ling, &c. is carried on on the great bank of Newfoundland, and on the neighbouring coasts. The former is now chiefly engrossed by the French and Americans; but the British fishery, although principally confined to the coasts of Newfoundland and Labrador, is very extensive. The following table shows the importance of the cod fishery to Newfoundland:—

FISHPONDS

	Quantities of Codfish exported	Value in Pounds Sterling
1855	1,107,388 cwt. .	680,283
1856	1,268,334 quintals	789,124
1857	1,392,322 " .	1,006,129
1858	1,038,089 " .	765,101
1859	1,105,793 " .	894,966

(Hind's *Explorations in Labrador*, chap. xiv.)

6. The Greenland whale fishery was engaged in by the English in the seventeenth century, but not with vigour until encouraged by a bounty in 1740. Since the close of the wars with the first Napoleon, it has declined in importance. In 1815, 146 vessels sailed; in 1834, 76 only. The southern whale fishery is a more modern branch of the traffic. (McCulloch, *Statistics of Great Britain*, ii. 21 &c.; article 'Fisheries' in *Encyclopædia Britannica*; Report of the Committee on the Channel Fisheries, 1833: the former writer estimates the annual value of the fisheries at about 3,000,000*l.* per annum.) The coast and sea fisheries are protected by a variety of enactments. (See the statutes collected 3 Steph. Black. p. 276.) Fishing vessels are licensed by the commissioners of customs under the Customs Acts. As to inland fishing, the law of offences in private fisheries is now consolidated by 24 & 25 Vict. c. 96. Taking or destroying fish in water running through or in land adjoining or belonging to the dwelling-house of the owner of the water, is a misdemeanour; in any water not within this description, but private property, or in which there is a private right of fishing, it is punishable with fine on summary conviction. Angling in the daytime is not within these enactments, but is punishable summarily with less penalty. The right of fishing in a river *primâ facie* belongs to the lord of the manor, who has the ownership of both banks. Fishery is said to be either *several* or *free*, or *common of piscary*. The first is in the owner of the soil, or one deriving title from him; the second is a royal franchise, conveying an exclusive right of fishing in a public river. Common of piscary is a liberty of fishery in common with others in a stream or river the soil whereof belongs to a third person, and resembles other commonable rights.

Fishponds. Ponds in which different kinds of fish are bred and fattened. In general this is only attempted with fresh-water fish; but in some places ponds have been formed on the seashore, and so contrived as to have their waters renewed every tide, and in these sea fish have been kept for use for a considerable time. The fresh-water fish most successfully managed in ponds are carp and tench.

Fissipara (Lat. *findo*, *I divide*, and *pario*, *I bring forth*). Those animals are so called which propagate by spontaneous fission, or the detachment of a greater or less proportion of the body, having inherent power of self-support and

FIXTURE

growth. As the animals which manifest this mode of generation differ widely among themselves in their general organisation, the term *Fissipara* cannot be applied to designate any natural group; spontaneous fission is limited to the lowest classes of animals, as *Infusoria*, *Polyps*; certain worms, as the *Nereis*, &c.

Fissiped (Lat. *fissipes*, *clown-footed*). In Zoology, a term applied to animals whose toes are not connected by a membrane.

Fissirostrals, **Fissirostres** (Lat. *findo*, and *rostrum*, *a beak*). The name of a tribe of perching birds (*Insessores*), comprehending the which have a very wide gape, as the:

Fissurella (Lat. *findo*). A genus of Gastropodous Molluscs, having a shell shaped like that of a limpet (*Patella*), but with a fissure at the apex of the cone, which opening is associated with a different form and arrangement of the breathing organs.

Fistula (Lat. *a pipe*). A long sinuous ulcer, often communicating with a larger cavity, and having a small external opening.

Fistulidæ, **Fistulidæ** (Lat. *fistula*, *a pipe*). A tribe of Echinodermatous animals, comprehending those which have an elongated cylindrical tube-like body.

Fitch. [VITEX.]

Fitchet. In Zoology, the polecat, or *Felis fatidus*.

Five Points. [ARMINIANS.]

Fixed Air. The old term for *carbonic acid*, from its existence in a fixed state in limestone, &c.

Fixed Oils. The common greasy oils are so termed in consequence of the high temperature which they sustain before giving out vapour.

Fixed Stars. Stars which retain the same or very nearly the same position with respect to each other. It has been discovered, by the accurate observations of modern times, that many of the stars have a proper motion. [STARS.]

In Law, a term generally applied to all articles of a personal nature affixed to land. This annexation must be by the article being let into or united with the land, or with some substance previously connected therewith. Thus a barn, built on a frame not let into the earth, is not a fixture; a brewer's stills, set in brickwork resting on a foundation, are fixtures; and the application of the same principle gives, in every case, the true rule to judge whether anything be a fixture or not. Whatever is thus fixed becomes, by law, parcel of the freehold or realty. It is, therefore, on general principles, not removable; but there are exceptions to this rule established by custom; of which the principal arise out the right of tenants to remove fixtures set up for purposes of trade, and in some instances for ornament and convenience (commonly called *tenant's fixtures*), and the right of executors to some fixtures, generally of the same description, as against the heir or devise of the realty. By the Act 14 & 15 Vict. c. 25 s. 3 useful erections by the tenant of a farm, put up with the consent of the landlord, were placed on the footing of tenant's fixtures.

FLABELLIFORM

Flabelliform (Lat. *flabellum*, a fan). In Botany, fan-shaped—as the plaited leaves of some palms.

(*Flacourtia*, one of the genera). A natural order of hypogynous Exogens, of the Violal alliance, sometimes known under the name of *BIXACEÆ* [which see]. In this group they are known by their leaves being either dotless or marked with round (not linear) dots, by their flowers being scattered, and either apetalous or polypetalous, and by their petals and stamens being both hypogynous. They are tropical trees or shrubs, and furnish in the case of some species of *Flacourtia* subacid edible fruit, and in that of *Bixa* the turpoto used for colouring cheese.

On board ship, the flag is employed to designate a vessel's nation and employment, and also as a means of communicating intelligence. The national flags are *standards*, ensigns, and pendants (pronounced *pennants*). British vessels bear in addition as a distinguishing mark the union jack. Flags of occupation are the particular emblems borne by admiralty and war department vessels, yachts of the several clubs, ships belonging to companies, pilot-boats, &c. Flags of intelligence are of three shapes, square, triangular, and burgees: they are of one or two colours, and each represents a number or letter. By combinations messages may be transmitted with great rapidity as far as a telescope can cover.

Flag-Mentenant. The immediate attendant upon an admiral. He communicates his orders to the several ships in the command, and performs duties which resemble, *mutatis mutandis*, the functions of an aide-de-camp in regard to a general officer.

Flag-officer. In the Royal Navy, an officer entitled to bear at the masthead of his ship his personal distinguishing flag. This privilege is limited to admirals, vice-admirals, rear-admirals, and commodores.

Flag-ship. In a fleet, that vessel which bears the admiral's flag, and to which all other ships look for orders.

Flagella (Lat. *vine shoots*: Virg. *Georg.* ii. 299). A term used by the older Botanists to denote the twigs or youngest shoots of plants.

Flagellants (Lat. *flagellum*, a whip). A sect of enthusiasts who first appeared in the middle of the thirteenth century, and being then repressed, sprang up again with renewed violence in the fourteenth. Beginning first at Cremona in Italy, the contagion of the example spread in a few years throughout Europe; and every city was infested by multitudes who went naked from the loins upward, and inflicted upon themselves several daily flagellations, with the idea of obtaining thereby merit in the eyes of God. They formed themselves into a society, and at first were innocent in their behaviour; but as their numbers increased, they gave way to great excesses, and were eventually suppressed by a holy war proclaimed against them by Pope Clement VI.

Flagelliform (Lat. *flagellum*). In Botany

FLAME

whip-shaped. A term applied to a long, pliant, like stem.

Appendages, on many Infusoria, proceeding from the anterior part of the body, and of which the terminations alone exhibit a vibratory movement.

Flagellum (Lat.). In Botany, a trailing shoot, such as that of the vine; the word is also sometimes used to denominate that form of stem called a *runner*.

Flageolet (Fr.). A wooden musical wind instrument, played with a mouthpiece, the holes and keys whereof are stopped with the fingers, in the same way as the flute.

Flagstones. Sandstones, calcareous sandstones, or argillaceous limestones of considerable hardness and toughness, very flatly bedded and more or less fissile, splitting into large thick slabs useful for paving, are called *flagstones*. Some of the best are the Yorkshire flags and those from Caithness; the former from the millstone grit and coal measures, the latter from the old red sandstone. England is very rich in rocks of this kind.

Flail (Ger. *flegel*, Fr. *flau*, Lat. *flagellum*). A wooden implement for threshing corn by hand. It consists of the handle or handstaff, which the labourer holds in his hand, and uses as a lever to raise up and bring down the swile, or part which strikes the corn and beats out the grain and chaff from the straw. The swile is joined to the handstaff by the caplins or couplings, which are thongs of untanned leather, and sometimes the skins of eels or of other fish. These thongs are passed through holes in the ends of the handle and swile, and made fast by being sewn together. The flail was in use among the Romans, though the prevailing mode of separating corn from straw among the nations of antiquity was by treading it out with cattle in the open air. In the colder parts of Europe, this could never have been generally the case for obvious reasons; and hence the flail was the universal threshing implement till the introduction of the threshing machine, which has now taken the place of the flail everywhere in this country. [THRESHING MACHINE.]

Flake white. A term often applied to the purest *white lead*.

Flame (Ger. *flamme*, Lat. *flamma*). When the temperature of inflammable gases or vapours is raised very high, and in the contact of air, they are said to *burst into flame*; if previously mixed with a due proportion of oxygen, or of atmospheric air, they *explode*. In the former case the combustion goes on only at the surface in contact with air, and is quiet and gradual; in the latter, every particle of the inflammable body being in contact with the supporter of combustion, the inflammation extends instantaneously through the whole mass. The nature of flame was first explained by Hooke in 1677 (in his *Lampas*); but the relation of the light to the heat of flames, and the whole philosophy of their constitution, was first developed by Sir H. Davy in his researches published in the *Philosophical Transactions* between 1816 and 1817.

FLAMEN

All the leading phenomena of flame are well exhibited by a large gas-flame burning from a wide orifice. It presents a hollow cone, the heat and light of which are confined to its exterior surface. A transverse section of such a flame exhibits a ring of light surrounding a central unignited core: the inflammable gas

or vapour may be drawn by a tube out of this central portion, as in the annexed figure, where *a* represents the tube inserted into the central non-luminous part of the flame, and where the abstracted inflammable vapour is again kindled at its extremity.

A flame may be extremely hot without being proportionately luminous, as is the case with the flame of hydrogen, which is scarcely visible in daylight, but the heat of which is shown by introducing into it a piece of fine platinum wire, which immediately becomes white hot, and emits abundance of light. The *light* of all flames is of a similar origin, and depends upon *solid matter* ignited and rendered incandescent by the heat of the flame: thus if magnesia or lime in fine powder be projected into the flame of hydrogen, the luminosity of the flame is immediately increased. Finely divided charcoal is the substance to which all common flames owe their luminosity. It is derived from the hydrocarbon produced by the decomposition of oil, wax, tallow, &c., as contained in coal gas; but as charcoal, unlike magnesia and lime, is itself combustible, it not only renders the flame luminous, but is burnt in the act of so doing, and passes off, in a well-regulated and perfect flame, in the invisible form of carbonic acid gas.

When flames are cooled, they are at the same time extinguished; hence a flame cannot be made to traverse or recede through a metallic tube of small bore; and a flame may, as it were, be bisected by a piece of wire gauze held transversely across it: in which case the smoke, gas, or vapour and charcoal go through, but not hot enough to inflame, having been cooled down by their passage through the metallic meshes; but by ———— lying a flame to this smoke, it may again ———— kindled. In this way the upper portion of the flame may be burnt, while the inflammation of the lower half is prevented by the interposed cooling medium. These experiments are best illustrated by the flame of a gas-burner, and the two cases just cited are represented in the annexed figures.

Flamen. The title applied by the Romans to the priests of any particular deity as distinguished from priests in general, the most important being those of Jupiter, Mars, and Quirinus (Romulus). [AUGUSTALIA.]

Flaminge. [PNEUMOPTERUS.]

Flange (perhaps connected with *flank*). The name given to the plate projecting from

FLEECE

the side of a girder, or piece of iron, by which it can be connected with another.

Flank. In Fortification, that part of the bastion which reaches from the face to the curtain. The flank of one bastion serves to defend the ditch before the curtain and face of the opposite bastion. [FORTIFICATION.]

Flank of an Army. The right or left side, as distinct from the front or rear.

Flannel. [WOOL.]

Flashings (perhaps connected with *Fr. flaque, a splash*). In Architecture, pieces of lead, or other metal, let into the joints of a wall so as to lap over the gutters, or other conduit pieces, and prevent the splashing of rain from injuring the internal work.

Flat (Ger. *platt*). In Architecture, that part of a roof laid horizontally, and covered with lead or some other metal.

FLAT. In Music, a character of the form *b*, which depresses the note before which it is placed a chromatic semitone. Thus *D b* signifies a semitone below *D* natural (*y*). On keyed instruments the short keys are the representatives of these flats and sharps.

Flat Fifth. In Music, an interval of a fifth depressed by a flat, called by the ancients *semidiapente*.

Flat Fish. [PLEURONECTES.]

Flatten a Sail. To extend it fore and aft, whereby its effect is lateral only.

Flattig. In Architecture, a coat of paint, which from its mixture with turpentine is enabled to be worked *flat*, or to be finished with a perfectly even unvarnished tone.

Flatulency (Lat. *flatus, blast*). A morbid collection of gas in the stomach and bowels, commonly symptomatic of constipation and indigestion, or of indulgence in certain kinds of vegetable food. Warm tonics, aperients, and well-seasoned animal food, with weak brandy-and-water as a beverage at dinner, are the usual and effective remedies.

Flax (Ger. *flachs*). The fibre of the *Linum usitatissimum*, which is spun into thread and woven into *linen* textures.

The flax is pulled a little before the seeds are ripe; it is stripped, and the stalks are then soaked in water, when fermentation running into putrefaction ensues, so as to destroy the foreign matters with which the fibres are blended in the plant. The flax is then dried, and broken or beaten and winnowed, so as to separate the fibrous from the other parts; these are afterwards heckled, and prepared for the spinner. (For an account of these operations, and of the machinery by which they are effected, see *Ure's Dictionary of Arts &c.* 'Flax'.)

Flca. In Entomology. [PULX.]

Flcam (Dutch, *vlies*; Fr. *flamme, a lanceet*). An instrument used by farriers to bleed horses and cattle.

Flèche (Fr.). In Fortification, a simple redan usually constructed at the foot of a glacis. [RADAN.]

Fleece, Order of the Golden (Fr. *toison d'or*). One of the most distinguished among

FLEET

European orders of knighthood. It was founded by Philip III., duke of Burgundy, in 1430 and as by its foundation his successors were declared to be hereditary grand masters, the title passed, with the Burgundian inheritance to the house of Austria; thence, after the death of Charles V., to the Spanish line of that house but when the monarchy of Spain passed to the Bourbons, and the Spanish Netherlands to Austria, the archdukes of Austria claimed the grand mastership; and claims are made on it at present both by the emperor of Austria and king of Spain. The order is consequently conferred both at Vienna and Madrid, and is, in both courts, the highest in point of rank. As its nominal object is the protection of religion, it is rarely conferred on any Protestants, with the exception, by courtesy, of Protestant sovereigns.

Fleet (A.-Sax. *flota*, a ship, Fr. *flotte*). In its most extended signification, this term is applied to a number of ships, pursuing in company either mercantile or warlike purposes, or both; but it is more generally confined to the different detachments which form the navy of any country, stationed in various parts of the world for the purposes of defence, aggression, or intimidation. [NAVY; SQUADRON.]

Flemish School. In Painting, the school formed in Flanders; established originally by the brothers Van Eyck at Ghent and Bruges at the commencement of the fifteenth century. It seems to have been allied to the old school of Cologne in its method of execution, but the Van Eycks exchanged the *tempera* vehicle for varnish. Memling, Roger Vander Weyden, Quintin Matsys, Mabuse and Antonij Moro were the great masters of the earlier period. Rubens and Vanduyck were the great masters of the second period, after it became the fashion to study in Italy. Snyder, Jordaens, Gaspar de Crayer, and the younger Teniers were also great masters. The works of this school are distinguished by the most perfect display of chiaroscuro; high finishing without dryness; by an admirable union of colours well blended and contrasted, and by a flowing luxurious pencil. But the Flemish painters, like the Dutch, represented Nature as they found her, and not as she should be. Rubens and Vanduyck, though men of the greatest genius, were not free from this defect. (*National Gallery Catalogue*, 1865; Michiels, *Rubens et l'Ecole d'Anvers*, Paris 1854; and the *Catalogue du Musée d'Anvers*, 1857.)

Fleta. The title of an ancient treatise on English law, attributed to the reign of Edw. I. and named (according to tradition) from its composition by a judge in the Fleet prison.

Fleur-de-Lis (Fr.). In Heraldry, a charge supposed to represent a lily: borne from a very early period in the royal arms of France. It is, however, more probable that the shape of this bearing was intended to represent the iron of a javelin.

Flexibility (Lat. *flexibilis*, *pliant*). That property of bodies in virtue of which, when a

FLINT GLASS

sufficient force is applied to them, they change their form, and are bent. Flexibility is opposed to *stiffness* on the one hand and to *brittleness* on the other; stiff bodies being such as resist bending, and brittle those which cannot be bent without a disruption of their parts. [STRENGTH OF MATERIALS.]

Flexor Muscles. In Anatomy, muscles the office of which is to bend the joints.

Flexuose (Lat. *flexuosus*, full of turnings). In Botany, applied to bodies which have a zig-zag or wavy direction, i.e. gently bending alternately in opposite directions, as in the case of some stems, the ribs of leaves, &c.

Flexura (Lat. *a bending*). In Mammalogy, the joint between the antibrachium and carpus, usually called the *fore-knee* in the horse; analogous to the *wrist-joint* in man.

Flexure. In Geometry, the bending or incurvature of a line or surface. A POINT OF CONTRARY FLEXURE is synonymous with a POINT OF INFLEXION; it is the point of contact of a STATIONARY TANGENT [see these terms].

Flint (Ger. *flins*). A variety of Quartz somewhat allied to Chalcedony, but more opaque and of dull shades of grey, yellow and black. Common flints are nearly pure silica. They occur in layers of irregular nodules and sometimes in flat tabular bands in the Chalk formation of England and the north of Ireland, in courses which are mostly parallel with the stratification. They often include organic remains, especially of infusoria, echini, shells and sponges. When two pieces of flint are rubbed together, they phosphoresce, and exhale a peculiar odour. After being calcined and ground, Flints are often used in the manufacture of earthenware and porcelain. They are also employed in Chalk districts as a building material and for making roads. [FLINT IMPLEMENTS.]

Flint Glass or Crystal. A species of glass which derives its name from flint, because that substance was formerly employed in its manufacture. It is extensively used for domestic purposes. Its dispersive power in regard to light renders it invaluable in the manufacture of the object-glasses of telescopes and microscopes; for by combining a concave lens of flint glass with one or two convex lenses of crown glass (which possesses a much less dispersive power), a compound lens is formed, in which the prismatic colours arising from simple refraction are destroyed, and the lens rendered achromatic. This construction of object-glasses was first discovered by Mr. Hall, a country gentleman in Worcestershire, about 1729; but the discovery was forgotten, and no further notice taken of it for nearly thirty years, when it was again brought to light by John Dollond, after a long-continued course of experiments undertaken for the purpose of perfecting the telescope. It is, however, very difficult to prepare flint glass fit for achromatic telescopes; owing to its imperfect homogeneity; the slightest inequality in this respect giving rise to a confused and imperfect image. The

composition of glass free from such faults long remained a secret in the family of the Dollonds, and its manufacture formed a profitable article of exportation; for till about the beginning of the present century, no flint glass of good quality was made on the Continent. Of late years, however, glass of the best quality has been manufactured, both in France and Germany, in much larger masses than our English artists had succeeded in obtaining before Chance's time. This was mainly brought about by the experimental researches of D'Artigues, Fraunhofer, Cauchoix, Guinand, and Kerner. Formerly, an object-glass exceeding five inches in diameter could scarcely be produced. Fraunhofer succeeded in making them of nine, and even twelve inches. There is a valuable paper on the manufacture of glass for optical purposes, containing the results of an extensive series of experiments upon the subject, made in the laboratory of the Royal Institution, by Mr. Faraday, in the *Philosophical Transactions*, vol. cxx.

Flint glass for common purposes is usually made of 120 parts of fine white sand, 40 parts of well-purified pearlash, 35 parts litharge or minium, 13 parts nitre, and a small quantity of the black oxide of manganese; the latter ingredient being used to correct the green colour occasioned by the presence of traces of oxide of iron. The principal difference between flint and crown glass consists in the large proportion of oxide of lead in the former. [OBJECT-GLASS.]

Flint Implements. From time to time, for at least three-quarters of a century, there have been suggestions and supposed discoveries of certain indications of human remains in rocks of a date anterior to the most ancient human records. Such indications, consisting chiefly of stony materials imperfectly sculptured, have attracted great attention for some years past, and their position has lately been clearly and satisfactorily determined. They have been found in and actually form part of gravels containing many bones of extinct gigantic animals, the inhabitants of the earth in times long past, mixed, occasionally though rarely, with bones of men. As most of these sculptured stones hitherto found in France and England consist of flints, they may properly be considered under the head of *flint implements*.

The precise nature of these implements, the fact that they must have been of human manufacture, and the clear proof of their position in situ with bones and other remains of animals contemporaneous with the savages who made the implements, are the points of chief interest.

They are principally composed of flint, but include granite, jade, serpentine, jasper, basalt, and other stones. Many of them are so slightly and roughly manufactured that they might of themselves escape notice; but some, and of these some in each important locality, are distinctly cut into definite shapes, always nearly the same, and corresponding in appearance with the hard stones still used by various savages for arrow-heads, axe-heads, lance-heads, and

rough knives. Some few are even more carefully finished and smoothed. The most numerous are flakes of flint apparently intended for knives. The most perfect are oval or almond-shaped stones. So large a number of them have been found in certain spots as to lead to the supposition that they have been intentionally buried, or that a manufactory of them existed there.

The chief localities for these objects, at first, were two or three gravel beds on the banks of the Somme, near Amiens and Abbeville, in France. Many caverns and some gravel beds in the southern and western parts of England have since yielded them. They have been found also in Belgium, Germany, and Italy, always with the same associations.

The evidence of their being of the age of the gravel deposit is varied and fragmentary, but on the whole satisfactory. In the first place, the gravel is undisturbed, and it is clear that all parts of the deposit must have been placed where we find them at some one time, and have since been covered up by a natural accumulation of subsoil and soil. The flints are found not at the top, nor always near the top, but occupying a definite place in the mass either with or below the bones of extinct quadrupeds, such as elephants and rhinoceroses. The naturally broken and rolled flints are weathered generally in a particular way, and these sculptured flints are weathered in the same way and to the same extent. The gravel occupies a position so much above any water level in the neighbourhood, that the general level of the whole land must have changed since the deposit, to account for its accumulation. In the case of the caverns, the implements are found sealed up with extinct bones, by a natural incrustation of limestone, and then, after being thus sealed up, deposits of more recent date have been heaped upon them. In some cases the implements have been found under the bones of animals that have either died on the spot or been dragged into the cave while undecomposed. Among such animals are bears, hyenas, rhinoceroses, elephants, and hippopotamuses, of extinct species. Horns of reindeer, on which are etched recognisable figures of the reindeer, have been found with implements and human bones in the South of France.

As a general result of this curious enquiry, it would seem that there must have been human inhabitants—savages like those of Australia, or half-civilised men like the Indians of North America—for a period so enormously more distant than the most ancient historic event, that the imagination shrinks from the consideration of the question. The actual bones of such men have been found, though rarely; but owing to a disinclination to consider the evidence, they have till lately been neglected.

Float Boards. The boards fixed to the rim or outer circumference of under-shot wheels, which receive the impulse of the water and communicate the motion to the wheel.

FLOAT STONE

Float Stone. A porous or spongy variety of quartz, which will float in water until the air contained in its numerous cavities is displaced.

Floated Lath and Plaster. In Architecture, plastering of three coats, in lime and hair mortar, of which the first is the *prieking up* coat, the second the *floating* coat, the third the *setting* coat, or fine stuff.

Floated Work. In Architecture, plastering made of a perfectly plane surface, by means of a tool, which is a long rule with a straight edge, called a *float*, working against *gauges*, or *screeds*, carried out upon the face of the wall and nicely adjusted for the purpose of guiding the floating rule.

Floating Battery. A ship protected by iron plates or otherwise, and armed with heavy guns for battering purposes. Its service is ordinarily limited to harbour or coast duty, and it may or may not have steam power, according to the degree of locomotion required.

Floating Meadows. Meadow lands, the surface of which is flat, adjoining a river or other source of water, with which they can be flooded or covered at pleasure. The water is turned on chiefly in the winter season, when it is more or less muddy, and leaves a deposit that serves as a kind of manure. It is also beneficial to plants by the substances which it holds in solution, and which the plants require as food, as well as by preserving a higher temperature in the surface soil than it could maintain through the winter if fully exposed to the action of the atmosphere; because, wherever water is in a fluid state, its mean temperature, and that of the bodies immediately in contact with it, must be above 32 degrees, and at that temperature the grasses common in British meadows will grow. There are probably other benefits which grass lands receive from being covered with water during a portion of the winter season, but these have not yet been satisfactorily explained.

Floating Screeds. In Architecture, strips of plaster arranged and nicely adjusted for guiding the *floating rule*. [FLOATED WORK.]

Flocci (Lat.). In Botany, the woolly filaments that are found mixed with the sporules of many *Gasteromycetous Fungi*. Also any wool-like hairs; hence the term *floccose*, applied to plants covered with loose woolly hairs.

Floccillation (Lat. *floccus*, a lock of wool). Picking the bedclothes. This is an alarming symptom in many acute diseases.

Floccous (Lat.). In Mammalogy, the tuft of long flaccid hairs which terminate the tail.

Floe. A name given to the surface ice which at the end of an Arctic winter is borne at the mercy of the winds over the ocean.

Flood. [DILUVIUM.]

Floodgate. A door, or gate, placed at the point of discharge of a large land drain, or sewer, into a river, for the purpose of allowing the escape of the inland waters, during the intervals of the tides, or of the high waters in the rivers. Generally speaking, they are ex-

FLOOR CLOTH

cutted with their hinges upon the upper side, and they open outwards; but they are occasionally made with vertical hinges, so hung that when the pressure of the inside waters exceeds that of the outside, the gates shall open.

Floor (A.-Sax. *flor*). In Architecture, the pavement, or boarded lower horizontal surface of an apartment. It is occasionally constructed of earth, brick, stone, or other materials; but more commonly it is understood to mean the timber structure used for the purpose. Carpenters include in the term the framed timber work on which the boarding is laid, as well as the boards themselves. The several kinds of floors in common use are known by joiners under the names of the *straight-joint floors*, *folding floors*, *herring-boned floors*, and *feather-tongued floors*. Of these, the *folding floors* are those in which the floor boards are so laid that their joints do not appear continuous throughout the whole length of the floor, but the boards occur in bays, or folds, of three, four, five, or more boards, each. *Straight-joint floors* are those in which the boards are so laid that the joints shall form a continuous line throughout the length; they are generally laid much closer, for their fixing must be effected by the use of dogs or screws. *Herring-boned floors* are those in which the floor boards are laid in short lengths at an angle of 45 degrees—they are principally used for wainscot floors; and *feather-tongued floors* are those in which a thin slip of wood, or metal, is inserted between the horizontal joints for the purpose of opposing the transmission of the dust, and for opposing the curling up of the edges of the boards; they are principally used for warehouse floors.

Floor. The lower part of a ship's bottom.

Floor Cloth. This useful and ornamented manufacture originated in this country about the year 1740, when a manufactory of it was established at Knightsbridge, near London. It was originally made of narrow canvas sewn together like sail cloth, to which successive coats of paint were applied; but the seams proving inconvenient, a canvas was wove for the purpose, about four yards wide; it was then extended to seven yards in width, and afterwards to nine. The manufactory at Knightsbridge is one of the largest establishments of the kind; the dimensions of the oil cloths produced there being twenty yards by eight, and thirty yards by seven. These canvases, being stretched upon frames, and accessible over their whole surface by stages erected for the purpose, render the large dimensions of the manufactory requisite. The canvas being duly strained is rubbed with pumice stone, which renders its surface smooth and even, and then brushed over with a weak solution of size; when this is dry, the first coat of oil colour is laid on, not with brushes, but with trowels, something in the manner of plastering; when this is dry, a second coat follows it; and in this way six coats of paint are usually applied in succession, two on the back and four on the front. When

FLORA

the cloth in this state, and of one colour, is sufficiently dry, it is removed from its frame upon a large roller, and carried to the upper part of the building to be *printed*; that is, to receive its pattern. This was originally effected by a process of stenciling; but in the year 1780 the great improvement of *block-printing* was introduced, by which the colours are more correctly laid on, and in greater body and variety. The printing table, which is about thirty feet long, four wide, and two feet six inches high, is firmly constructed of deal timbers laid edgewise and clamped together, the surface being truly planed; the roll of painted cloth is placed underneath it, and as it is unrolled it gradually passes over the table, where it is printed, and is then drawn forward so as to hang perfectly free while drying, the height of the building being such as conveniently to admit of this, without rolling, doubling, or folding the material, which in these stages would of course injure it. The colours, which are the usual oil colours very carefully prepared, are put on in succession with wooden blocks, which are made of pear-tree, box, or holly wood, and upon which the patterns are cut in relief; they are about eighteen inches square, and are applied in succession over the whole of the surface of the cloth lying upon the printing table. Every colour is put on by a separate block, and much dexterity is required in so placing them that the patterns may correctly interlace and join each other, without in any case overlapping or interfering: to effect this the workman is aided by guide pins, or *pitchers*, as they are termed, which direct him in placing the block. The colours are first brushed or tiered upon hard cushions, from which they are transferred to the block, and thence to the cloth; and, though many are often required, it is astonishing how much effect is sometimes obtained by the judicious arrangement or mixture of two only, upon a third, which forms the ground. It will be obvious, from what has been stated, that the weight of the finished oil cloth, as compared with the naked canvas, is no unimportant criterion of its goodness; each square yard when finished weighing from four to five pounds: this distinguishes a good oil cloth from those which are ramped up and stiffened with size and other perishable materials.

Independent of the common application of oil cloth, it is not unfrequently advantageously employed as a roofing material, especially for covering verandahs and other light structures. When used for this purpose, the canvas should be made of picked long flax, and thoroughly saturated with good oil paint; it will then stand our climate and last for fourteen or fifteen years. [KAMPULICON.]

Flora. In Astronomy, a planet belonging to the group between Mars and Jupiter. [ASTRONOMY.]

Flora. The plants peculiar to any country constitute its flora. [FAUNA.]

Floral Envelopes. In Botany, this term is applied to the calyx and corolla if both are

FLOUR

present, or to the calyx when there is only one. These parts envelope or protect the more essential organs, stamens and pistil.

Florets. The flowers of a capitule or anthodium; which are often smaller in size, but not different in structure from ordinary flowers. Those which are placed in the middle of the capitule are called *discoidal*, or *of the disc*; those in the circumference are named *radiant*, or *of the ray*.

Floria. [MONAY.]

Flos-ferri (Lat. *flower of iron*). A coralloidal carbonate of lime, often found in veins of spathose iron ore.

Flota. A name given by the Spaniards to the ships that formerly sailed together, or under convoy, from Cadix and the other ports of the Peninsula authorised to trade directly with the Transatlantic possessions of Spain. The word is identical with our *fleet*.

Flotilla (Span.). Literally, *a little fleet*; in which sense, however, it is seldom used, being applied almost invariably to a fleet, how large soever, composed of small vessels. Thus the term *flotilla* was given to the immense naval force with which Napoleon meditated the invasion of Great Britain, and which consisted of 2,365 vessels of every description, was manned by about 17,000 sailors, and carried 169,000 soldiers with 10,000 horses. In Spain, the name *flotilla* is given to a number of vessels appointed to announce to the home government the departure and nature of the cargo of the flota or mercantile ships from foreign ports on their homeward voyage.

Flotsam (floating), **Jetsam** (Fr. *jeter*, to throw), and **Lagan** (lying), as Law terms, are usually joined together. The first, according to Blackstone, designates goods cast from a ship and swimming in the waves; jetsam, goods cast and sunk; lagan, sunk but tied to a buoy by the owners. Goods in either of these three predicaments belong to the king, if the owners be not known, and may by him be granted with other franchises.

Flounder. In Ichthyology. [FLOXA.]

Flour. The finer portion of the meal to which grain is reduced by grinding. It is separated from the bran, middlings, pollards, &c., with which in *whole meal* it is mixed, by passing through sieves and *silks* which allow its passage but hinder that of the coarser meal. The following is a short description of the whole milling process.

Mill stones are circular slabs of French burr (about four feet across and nine or ten inches thick), pieced together and held in one by an iron rim. Their surfaces are made perfectly true planes; they are pierced at the centre by two circular eyes about six inches in diameter. The lower one is fixed and firmly bedded; the upper one hangs balanced on cross bearings on the end of the vertical shaft (passing through the eye of the lower one), by which it is driven. It is furnished with four leaden plugs around its upper circumference, by additions to which it can be accurately balanced, and the shaft is

FLLOUR

then lowered until the two surfaces are on the point of touching one another. The grain is fed into the interval between them through the eye of the upper stone; and the centrifugal tendency consequent on its revolution, together with blast and exhaust respectively where Bovill's patent is employed, drives it from the inner to the outer edge of the grinding surfaces, the grain being reduced to flour and bran on its way. In order to accomplish this result, the surfaces of the stones are furrowed, so that both rubbing and cutting are combined in the process of grinding.

In the first place each surface is scored with ten tolerably deep equidistant radial grooves, and thereafter the angular sections thus defined are tooled with straight and equidistant close and shallow furrows chipped out, which are not radial, but which are parallel to the foremost of the radial sides of each section as the whole revolves. When this one surface revolves over the other, which it does at the rate of about 120 revolutions per minute, the scorings of the under and upper surfaces cross one another and produce a cutting as well as a rubbing of whatever lies between them, while their action tends somewhat to check the rapidity of the centrifugal action upon the still unground fragments of the berry of wheat which have yet to be reduced to flour. A week's grinding so far obliterates these markings on the stones as to require them to be re-dressed. A steel straight-edge is used by which to make wooden ones, and the latter when thus made absolutely true indicate by means of paint any faults of surface in both the stones, and thus in retooling, the scores upon the stones the perfect truth of the surfaces employed is insured. A good stone will wear not more than an inch in seven years.

The further process is best described by means of a particular example. As the flour and bran, &c., leave the stones, they fall down a tube into the floor below, and the whole is then received by a horizontal tube with screws, which conveys it along to the various lifts by which it is carried up into an upper floor, where it is dressed, i.e. separated into the various qualities, bran, pollards, &c., and fine flour; and thence it drops into the flour rooms or *pastries*, from which it drops into sacks.

The dressers are *sills*—cylinders of silk, of varying texture, in this instance thirty-six feet long, and about three feet in diameter, stretched upon octagonal frames, revolving at the rate of twenty-six per minute—into which the whole meal is received, and through which the flour passes into the *pastries* below, while the bran is delivered into shoots and carried by lifts, &c., to the store, whence it is delivered for sale. In this way the whole produce of the stones is separated into the various sorts and qualities known in the market, which have been already enumerated. It must be added that before wheat is delivered to the mill-stones, it is cleaned, in fact scrubbed, in order to get rid of bunt and smut, riddled to get rid

FLUIDITY

of chaff and weed seeds, and various qualities are mixed so as to insure flour of the strength and character desired. [BREAD.]

Flower (Lat. *flos*, Fr. *fleur*). In Botany, the term applied to that assemblage of organs of which the stamens or pistils, or both, form part. In many, indeed most, cases these are enclosed by two whorls called *calyx* and *corolla*, but the latter are not essential to the idea of a flower.

Flowerless Plants. Those plants that are destitute of flowers and sexes. They are the same as *cryptogamic*, or *acrogenous*, or cellular plants.

Flowers. The old chemists gave this name to several light flocculent substances obtained by sublimation; such as *flowers of sulphur*, *flowers of benzoïn*, &c.

Fluocine or Fluocerine. The native fluoride of cerium, occurring near Fahlun, in Sweden.

Fluellite. Native fluoride of aluminum, occurring at Stenagwyn, in Cornwall.

Fluent or Flowing Quantity. In Analysis, the variable quantity, considered as increasing or diminishing. The term denotes the same thing as *integral*, which is now universally used in its stead, the differential and integral calculus having superseded the methods of fluxions and fluents. [FLUXION, INTEGRAL.]

Fluid or Fluid Body. A body whose parts yield to the smallest pressure, and are moved among each other without any sensible resistance.

Fluids are of two kinds, elastic and non-elastic. The mechanical properties of elastic fluids, comprehending air and the different gases, constitute the science of *Pneumatics*; those of the non-elastic fluids, water, mercury, &c., *Hydrostatics* and *Hydraulics*. It is to be remarked, however, that the terms *elastic* and *non-elastic* are here used in a relative, not in an absolute sense; for water, alcohol, and probably all other fluids of the same class, are, to a certain extent, compressible and elastic, though they resist compression with a very great force.

Fluid Ounce. [MEASURES.]

Fluidity (Lat. *fluidus*, from *fluo*, I flow). That state of a substance in which its constituent particles are so slightly cohesive that they yield to the smallest impressions. The term is usually confined to express the condition of the so-called non-elastic fluids; and hence it denotes one of the three states in which matter exists; namely, the solid, the fluid or liquid, and the gaseous. The state of fluidity is best defined as that in which bodies tend to form *drops*, as this disposition does not belong either to bodies in a gaseous form, or to solid bodies reduced to fine powder. The formation of drops arises from this—that the molecules of fluid bodies adhere to each other with a certain force, while at the same time they glide over one another without any sensible resistance. It is incorrect to say that the molecules of bodies in a state of

FLUKE

fluidity offer no resistance to separation; for, on bringing a flat disc of glass or metal into contact with the surface of a liquid, a very sensible degree of force is required to separate them. That adhesion exists among the molecules of fluid bodies, is also proved by various other phenomena. Water or mercury on a flat plate of metal collects in globules, and when slowly poured into a wineglass will remain heaped up as it were above the level of the edge.

Fluke. A name commonly applied to a species of flat fish, or *Pleuronectes*, also termed *flounder*; and also to an *Entozoon* of a similar form (*Distoma hepaticum*), which infests the ducts of the liver of different animals, especially of the sheep.

FLUX is also applied in Navigation to the broad pointed part of the anchor which takes hold of the ground.

Fluoboric Acid or Fluoride of Boron. A gas obtained by heating to redness a mixture of dry boracic acid and powdered fluor spar. Its specific gravity is 2.36. It is colourless, pungent, and produces a dense white cloud when it escapes into a moist atmosphere; it is resolved by the action of water into boracic and hydrofluoric acids. It acts with great energy upon animal and vegetable substances, and chars them. It is a compound of one atom of boron and three atoms of fluorine.

Fluor Spar. A common mineral product, which frequently constitutes a large part of the contents of metalliferous lodes, and of veins in clay-slate. In many mines of Devon and Cornwall, especially in some of those situated in or near granite, it forms an important constituent of the matrix of the copper ores. It is generally crystallised in cubes, but the primary form is a regular octahedron. It is a fluoride of calcium, composed of 51.3 per cent. of calcium and 48.7 fluorine. The colours are very various, but generally white, grey, or tints of blue, green, purple and yellow. The varieties found in Derbyshire are known in this country under the name of *Derbyshire Spar*, and locally by the miners as *Blue John*: These are often beautifully banded, especially with blue and purple, and are much prized for the manufacture of vases; they are also occasionally made into beads, brooch-stones, and other ornamental articles. Fluor spar is also used as a flux to promote the fusion of certain refractory minerals, for which reason it has received the name it bears (from *fluo*, to flow). Small quantities of fluoride of calcium are found in some organic products, and in certain mineral waters. [**FLUX.**]

Fluorescence. The peculiar self-luminous appearance presented by certain substances on being viewed by reflected light. A particular kind of *fluor spar* was first observed to have this property, hence the name *fluorescence*. Decoction of horse-chestnut bark and solutions of quinine possess it in a remarkable degree. The particular rays of light reflected to the eye of an observer from fluorescent bodies are in-

FLUX

visible except through the medium of such bodies. Even the spectrum produced by decomposing a pencil of light by a prism, gives to the unaided eye no evidence of their presence; it is only when a fluorescent body is introduced into their path that they are rendered visible. As these are refracted by the prism beyond the extreme violet, their frangibility is reduced to such an extent as to bring them within the limits of the visible spectrum.

Fluoric Acid. [**HYDROFLUORIC ACID.**]

Fluorine. The hypothetical base of the fluorides and hydrofluoric acid: it has not yet been obtained in a separate state.

Fluosilicic Acid. A gas obtained by applying a gentle heat to a mixture of one part of powdered fluor spar, one of silica, and two of sulphuric acid, in a retort. It is colourless, pungent, fumes when it escapes into a humid air, and is rapidly absorbed by water. Its specific gravity is about 3.6; 100 cubic inches weighing nearly 112 grains. It is decomposed by water, and forms silica and hydrofluoric acid. It consists of 22 parts by weight of silicon and 57 of fluorine, its equivalent (upon the hydrogen scale) being 79.

Flush. In Architecture, the continuance in the same plane of the surfaces of two contiguous bodies is expressed by saying that they are *flush*; this is irrespective of the direction of the fibres or grain.

FLUSH. In Maritime language, refers to the deck of a ship, and signifies that it extends without break of level from stem to stern; as in a frigate.

Flutes. In Architecture, the upright channels on the shafts of columns, usually ending hemispherically, at the top and bottom. Their plan or horizontal section is sometimes semicircular, or segmental, or elliptical, as in some examples of Grecian architecture. The Doric column has twenty flutes round its circumference; the Ionic, Corinthian, and Composite, have respectively twenty-four; the Tuscan column is never fluted, but it is occasionally **CABLED** [which see].

Fluviales (Lat. from *fluvius*, a river). A natural order of Endogenous water plants common in all extra-tropical countries, and approaching somewhat to flowerless plants. They belong to the Hydral alliance, and are specially marked by their hypogynous stamens, globose or filamentous pollen, free ovary, and complete embryo. Pollini, according to De Candolle, asserts that spiral vessels exist in them, while Amici urges the contrary. Their sensible properties are unimportant. *Zostera* or Sea Wrack, one of the genera, is used to stuff cushions, and as a material for packing. The order is often called *Nasadacea*, and according to the above definition includes also *Zosteraceae*.

FLUX (Lat. *fluxus*, flowing or loose). Applied in technical Chemistry to substances which are in themselves very fusible, or which promote the fusion of other bodies. When tartar is deliquescent with half its weight of nitre, a mixture of charcoal and carbonate of

FLUXION

potash remains, which is often called *black flux*: when an equal weight of nitre is used, the whole of the charcoal is burnt off, and carbonate of potassa remains, which, when thus procured, is called *white flux*.

Fluxion (Lat. *fluxio*, a *flowing*). In Analysis, the same thing as *differential*, the term being suggested by a particular view of the manner in which variable quantities increase or diminish. Newton considered a curve as generated by the uniform motion of a point, and decomposed at every instant by the constant velocity of this point into two others, one parallel to the axis of the abscissa, and the other parallel to the axis of the ordinates. These velocities are what he called the *fluxions* of the coordinates; while the arbitrary velocity of the point which describes the curve is the fluxion of the arc. Reciprocally, the arc described is called the *fluent* of the velocity with which it is described by the moving point; the corresponding abscissa is the fluent of the velocity estimated in the direction of the abscissa, and the ordinate the fluent of the velocity of the point estimated in the direction of the ordinate. The same considerations may be extended to the areas bounded by curve lines, to surfaces and the volumes which they determine, to forces which give rise to motion in bodies, and to the effects which they produce. In fact, the theory is applicable to everything which forms the object of the mathematical or physico-mathematical sciences.

The method of fluxions is derived naturally from that of *prime* and *ultimate ratios*; for the variable velocity of a point is not the path described time divided by this time; but

that quotient, that is to say, the quantity to which that quotient approaches more and more in proportion as the time is supposed to be shorter. This observation has occasioned an objection to the method of fluxions—namely, that of introducing into geometry, which is a branch of the pure mathematics, the idea of velocity, which belongs to the mixed mathematics; and of defining an idea which ought to be simple by one that is complex. The objection is unimportant; the main question being whether the theory is more easily apprehended by this manner of exposition than by any other.

In applying the method of fluxions to mathematical investigation, the procedure is precisely the same as in the differential calculus; from which it differs in no respect save that of notation. The method was invented by Newton; and his notation was adopted by all English writers, and long obstinately adhered to, although the notation of Leibnitz, the inventor of the differential calculus, possesses over it many advantages, particularly in the more abstruse theories of analysis.

The best systematic *Treatise on Fluxions* is that of Maclaurin, published at Edinburgh in 1742; the first treatise on the subject, in our page, in which the differential notation employed throughout, was the article

FLYSCH

'Fluxions' in the *Edinburgh Encyclopedia*, which appeared in the year 1816.

Fly. In Entomology. [MUSCÆ.]

FLY. In Mechanics, an appendage given to machines for the purpose of regulating and equalising motion; and sometimes for collecting force in order to produce a great instantaneous impression, as in a coining press. Generally it is formed of a heavy disc or hoop at right angles to the axis; sometimes of heavy knobs at the extremities of a bar having the same position. The fly is of great use in all cases where the power, or the resistance, acts unequally in the different parts of a revolution.

Fly Powder. An imperfect oxide of arsenic, formed by the exposure of native arsenic to the air; when mixed with sugar and water it is used to kill flies.

Fly, Spanish. [CANTHARIDES; LITTA.]

Fly-catcher. [MUSCICAPE.]

Fly-wheel. The large wheel of a steam engine which is introduced for the purpose of carrying the piston over the dead points of the stroke, or for the purpose of regulating the velocity of the motion, so as to prevent unequal strains upon the driving gear. The fly-wheel is placed upon the first motion wheel in the majority of cases, and is made of sufficient weight to regulate the movements of the engine.

Flying Buttress (called in Fr. *arc boutant*). In Gothic Architecture, a buttress in the form of an arch, springing from a mass of masonry, on the external wall, and abutting against the springing of another arch, which rises from the upper points of abutment of the first. Its office is to discharge the weight of the clerestory roof, or the vaulting of the nave, to the points of the external walls where the resistance is increased by the introduction of the pinnacles over the buttresses. If the buttresses were built directly under the points of discharge of the arches, it is evident that they would interfere with the vista along the aisles of the church; and hence they are carried down on the outside. Their stability depends on the dead weight of the buttresses from which they spring.

Flying Fish. The species of two distinct genera of fish, in which the pectoral fins are so developed as to enable them to sustain themselves for a short time in the air, are so called. The more common species are the Mediterranean flying fish (*Exocoetus volitans*) and the flying gurnard (*Dactyloptera volitans*).

The word *exocoetus*, Gr. *ἐξωκωτος*, strictly denotes an animal which comes out of the sea to sleep, and would thus be applied to seals, walruses, &c.

Flying Jib. In Navigation, a triangular sail set outside, i.e. before, the jib.

Flying Sap. In Military Engineering, the rapid excavation of the trenches of an attack, when each man advances under cover of two gabions.

Flysch. A name given to a part of the great nummulitic formation in the Alps where

the rock passes into metamorphic limestones, and even into crystalline mica schists and gneiss. These beds are not always limestones, even when loaded with fossils of foraminifera. [NUMULITIC FORMATION.]

Fo. The name given by the Chinese to Buddha. Originally the name Buddha was expressed in the Chinese language with sufficient exactness by the term Fô-thau, pronounced Fô-dah; but, as is usual in China with proper names, the last syllable was subsequently dropped. According to the Chinese historians, the religion of Buddha was introduced into China in the reign of Ming-ti, of the dynasty of the Hans, about the sixty-fourth year of the Christian era; but there is good reason to believe that the doctrines of the Indian reformer had been carried thither before that period, and that it is only to their official recognition by the government that this later date refers. In China the same principles are adopted as in all countries where Buddhism is professed, with the exception of a few trifling deviations which the various translations of the Buddhist writings from their original Sanscrit have naturally generated. (For the results of recent researches on this subject, see *Le Bouddha et sa Religion*, by M. Barthélemy St. Hilaire.)

Focal Conics of a Quadric Surface.

[Focus.]

Focal Lines of a Quadric Cone.

[Focus.]

Foci of an Involution. [INVOLUTION.]

Focle Majus. In Anatomy, the greater bone of the arm or the leg, the lesser being termed *focle minus*.

Focus (Lat. a *hæretis*). In Optics, the point in which rays of light are collected by refraction or reflection. A mirror, for instance, whose reflecting surface coincides with that of a paraboloid of revolution has the property of causing all rays which are incident parallel to its diameter, to pass, after reflection, through the same point. Again, in the major axis of an ellipse there are two points, such that any ray of light proceeding from the one is reflected through the other; and in the transverse axis of an hyperbola there are also two points, from either of which if rays were to emanate, they would, after reflection, proceed as if they emanated from the other. In virtue of these optical properties the term *focus* became introduced into the geometrical theory of conic sections. Subsequently it was found that these same points possessed other properties more suitable for their geometrical definition. It was found, for instance, that to each focus of a conic there corresponds a right line, known as the *directrix* or polar of the focus with respect to the conic, such that the ratio of the distances of any point of the conic from the directrix and the focus is constant. If $L=0$ represent, in rectangular Cartesian coordinates with the focus for origin, the equation of the directrix, the property under consideration is expressed by the equation $x^2 + y^2 = a^2 L^2$. But in this form,

to which the equation of every conic is reducible, we at once recognise that the two imaginary lines $x+y\sqrt{-1}$, $x-y\sqrt{-1}$ which join the focus to the circular points at infinity touch the conic. We are thus led to define the foci of a conic, and by generalisation the foci of any curve whatever, as the points of intersection of the tangents to the curve drawn through the circular points at infinity. For a curve of the n^{th} class there will consequently be n^2 foci: of these, however, never more than n can be real, since no imaginary tangent can pass through two or more real points. The above general definition of foci, as well as an investigation of the focal properties of cubic and other curves, will be found in Salmon's *Higher Plane Curves*.

The foregoing equation shows also that a focus of a conic may be defined as the point-circle which has double contact with the curve and the corresponding directrix as the chord of contact. The advantage of this definition is that it may be extended to quadric surfaces, a focus of which may be defined as a point-sphere having double contact with the surface, the corresponding directrix being the chord of contact. Thus (ξ, η, ζ) will be a focus, if the equation of the quadric can be expressed in the form

$$(x-\xi)^2 + (y-\eta)^2 + (z-\zeta)^2 = AL^2 + BM^2,$$

where $J=0$ and $M=0$ represent planes which intersect in the corresponding directrix, and A and B are constants. The section of a quadric made by any plane through a focus and its directrix is always a conic having its own focus and directrix coincident with those of the surface. According as A and B have unlike or like signs, the planes of contact of the point-sphere and quadric will be real or imaginary. In the former case the planes of contact are parallel to the planes of circular section of the quadric, and in the latter case the point-sphere is distinguished as a *modular focus*, since the distance from it of any point on the quadric bears a constant ratio, the reciprocal of which is called the *modulus*, to the distance of the same point from the directrix, this latter distance being measured parallel to one of the planes of circular section. It can be shown readily that every quadric has innumerable foci, all of which, however, lie in three plane conics, called the *focal conics*, situated in the principal diametral planes of the quadric. Of these three focal conics, in the case of central quadrics, one is always imaginary, one an ellipse, and the other an hyperbola. The focal conic which contains the modular foci is called the *modular focal conic*, and does not intersect the surface. On the other hand, the focal conic which contains the *non-modular foci* always intersects the quadric in its umbilics, and has on that account been denominated the *umbilical focal conic*. In the case of an ellipsoid whose semi-axes are $a > b > c$, for instance, the modular focal conic is the ellipse $(\sqrt{a^2 - c^2}, \sqrt{b^2 - c^2})$ confocal with the elliptic section (a, b) ; the umbilical focal conic being the hyperbola $(\sqrt{a^2 - b^2}, \sqrt{b^2 - c^2})$.

FOCUS OF A PLANE

confocal with the elliptic principal section (a, c) and passing through the umbilics whose co-ordinates are given by the equations

$$x^2 = a^2 \frac{a^2 - b^2}{a^2 - c^2}, y = 0, x^2 = c^2 \frac{b^2 - c^2}{a^2 - c^2}$$

In the case of cones, the focal ellipse coincides with the vertex, and the focal hyperbola degenerates into two right lines through the vertex which take the name of *focal lines*. The numerous properties possessed by the foci of quadric surfaces were discovered independently and at about the same time by Charles and McCullagh (*Aperçu Historique et Proceedings of Royal Irish Academy*, vol. ii.). Townsend in the *Cambridge and Dublin Mathematical Journal*, vol. iii., and Salmon in his *Treatise on Surfaces*, have also given able expositions of these properties.

Focus of a Plane. [KINEMATICS.]

Fodder (A.-Sax. *voder*, Ger. *futter*, *food*). In Agriculture, whatever is given to cattle as the ordinary food is designated *fodder*; whereas corn, beans, and other articles, which present nourishment in a more concentrated form, are not included under the term *fodder*, but are rather known as *solid food*.

FODDER (A.-Sax. *foder*, a *cart*, hence a *load*). The name of a weight formerly used in the weighing of lead: it was of various magnitudes, but most commonly about 2,400 lbs.

Fœniculum. [FENICULUM.]

Fœtus (Lat.). From about the fifth month after pregnancy till the period of its birth, the child in the womb of its mother is termed a *fœtus*.

Fog (Dan.). In Meteorology, a cloud resting upon or near the surface of the land or water. Fogs, in general, are the consequence of the cooling of atmosphere. When humid air is cooled, a part of its moisture separates in the form of visible vapour or fog. During the day the heat of the sun generally disperses the fog, because the quantity of moisture which the air is capable of holding becomes more considerable in proportion as its temperature is increased; and, thus as the temperature rises, the globules of water constituting the cloud gradually assume the form of true vapour, which is always transparent and invisible.

In calm weather the surfaces of rivers, lakes, &c. are frequently in the morning covered with fog. The reason is this: During the night the air is colder than the water; the strata of air in contact with the water are consequently heated, and become saturated with moisture. The mixture of the vapour with the air, together with its higher temperature, renders it specifically lighter. It rises in consequence, and mixing with the cold air in the superior strata, is cooled, and precipitates moisture. The cloud or fog resulting from this precipitation can only rise to a small height, because the uniformity of temperature is soon restored. Hence it is easy to see how winds, or agitation of the air, prevent the formation of fogs over the surface of water. In the equinoctial regions, fogs some-

FOLIAGE

times continue during a considerable part of the year. Humboldt relates that Lima is often covered with a fog half the year, especially in the mornings and evenings; and that along the whole of that coast fogs supply the place of rain, which is extremely rare. In the polar seas thick fogs often prevail even during the warmest months; and they are so dense that objects frequently cannot be distinguished at the distance of a few yards.

Sometimes, though rarely, fogs occur of which the cause is not well understood. In 1783, the whole of Europe was covered with fog during nearly two months. On May 22, 1822, about five o'clock in the afternoon, a fog covered Paris and the neighbourhood, which had the odour of nitrous gas: it continued about an hour. The yellow fogs of London derive their tint and odour from coal-smoke. The dust, ashes and vapours of volcanoes sometimes occasion peculiar forms of fog, extending over large and even distant districts. The dry fogs, or hazes, in which no precipitated moisture is present, have as yet been very imperfectly investigated.

Fog-rings. Banks of fog arranged in a circular or ring-form; a meteorological phenomenon not unusual on the coast of Newfoundland. (*British Association Report for 1846.*)

Foil (Fr. *feuille*, Lat. *folium*, a *leaf*). This term is generally applied to varnished metal. Common foil is manufactured as follows: A copper plate, covered with a thin layer of silver, is rolled out into sheets under the flattening mill; the silver surface is then highly polished and covered with a colourless varnish. The *coloured foils* are similarly prepared with coloured varnishes.

Foils. Thrusting swords with covered points using in fencing.

Folcland. [BOCLAND.]

Fold (A.-Sax. *fald*). A temporary enclosure for keeping agricultural animals together, either for the purpose of protection during night, or jointly for protection and feeding. Sheep are sometimes folded for the purpose of manuring. Folds are commonly constructed with wooden hurdles; but sometimes, when the fold is only to contain ewes and lambs, netting stretched between posts is made use of, a strong rope being fixed to the lower parts of the posts close to the ground, to which the under edge of the netting is attached, while its upper edge is attached to a rope stretched along the tops of the same posts. The practice of folding sheep on naked fallows, with a view to manuring them, is still common in several parts of England, and the South Down breed of sheep is especially adapted for it.

Foliage (Lat. *folium*, a *leaf*). In Architecture and Sculpture, a group of plants and flowers so arranged as to form architectural or sculptural ornaments; as in friezes, panels, architraves, &c., and also in the capitals of the Corinthian and Composite orders, in Gothic capitals, finials, crockets, &c.

FOLIATION

Foliation. One of those structural phenomena of rocks, the origin of which is obscure, but which are so large, and range so widely, that they must belong to the action of some important law. Gneiss, hornblende schist, mica schist, and even porphyries and basalt are often thus foliated, separating into plates of definite thickness. Very remarkable examples of foliation are described by Mr. Darwin as occurring in South America.

FOLIATION. In Botany, the manner in which the nascent leaves are arranged within a leaf-bud.

Folio (Ital. *a leaf*). In Account-books, signifies *page*. Thus *folio 7*—written abridgedly *fo. 7*—denotes the seventh page; *folio recto*, or *F^o R^o*, signifies the first page, *folio verso*, or *F^o V^o*, the second page of a leaf. A book in folio, or simply a folio, is one in which the sheet is only folded in two, each leaf making half a sheet.

Folio. In Printing, this term denotes the running number of the pages of a book. When there is no running head, the folios in Arabic figures are placed in the centre of the headline, sometimes between brackets or parentheses, but now usually without; where there is a running head, the folio is put into the corner.

Folium. A leaflet borne upon the axis of a leaf.

Folium of Descartes. A curve of the third order defined by the equation $x^3 + y^3 = 3axy$. It has a double point at the origin, and is consequently a cubic of the third class. The equation of its asymptote is $x + y + a = 0$.

Folk-mote. Among our Anglo-Saxon ancestors, signified any popular or public meeting of all the folk or people of a place or district; for instance, of all the tenants at a court-leet or court baron, or of all the freemen of the county, or of all the barons of the kingdom. Antiquaries are, however, by no means agreed as to the nature of the folk-mote; some considering it an institution of great, others of minor importance.

Follicle (Lat. *folliculus, a small sack*). In Anatomy, this term is applied to a simple gland, consisting merely of a hollow vascular membrane and an excretory duct: hence the term *mucous* and *sebaceous follicles*.

Folliculus (Lat.). A one-celled, one or many seeded, one-valved, superior fruit, dehiscing by a suture along its face, and bearing its seeds at the base, or on each margin of the suture; it differs from the legume in having but one valve instead of two.

This term has also other significations; viz.

1. According to Linnæus, any kind of capsule.
2. The cases bearing the reproductive organs of *Equisetaceæ*.
3. According to Gærtner, a double, one-celled, one-valved, membranous, coriaceous capsule, dehiscing on the inside, and either bearing the seed on each margin of its suture, or on a receptacle common to both margins; as *Asclepius*, &c.
4. According to Willdenow, any oblong pericarp bursting longitudinally on one side, and filled with seeds; as *Vinea*.

FOOD

Fomalhaut. A star of the first magnitude in Piscis Australis.

Fomes (Lat.). In Medical language, this term is applied to porous substances capable of absorbing and retaining contagious effluvia. Wood and woollen clothes are said to be active *fomites*.

Font (Lat. *fons, a fountain*). In Architecture and Sculpture, a vessel, generally of stone or of marble, for the purpose of containing the water of baptism in the Christian church. The fountains of Ewelme; All Saints', Norwich; Bradford Abbas, and Walsingham, may be mentioned as splendid specimens for the richness of their decoration and the character of the designs. (Paley *On Baptismal Fonts*; Simpson, *Baptismal Fonts*, &c.)

Font of Type. [FOUNT.]

Fontanel. The interstice or *mould*, as it is often called, which exists at birth between the frontal and parietal bones: it is closed by bony matter about the end of the third year.

Food (A.-Sax. *foda*). All substances susceptible of digestion and assimilation may come under the denomination of *food*; but the proximate principles of organic bodies on which their nutritive powers depend are comparatively few. Hence, although the articles employed in different countries for the support of animal life are almost infinitely various, their sustaining powers may be referred to certain substances capable of being separated and identified by chemical analysis and tests. Amongst the proximate elements of vegetable food, gluten and its modifications, starch, gum, sugar, and lignin or woody fibre, are the most important; and amongst those of animal food, fibrin, albumen, gelatine, and their modifications; together with fats and oils, which are common to both kingdoms of nature.

To illustrate the actual simplicity of our food as compared with its apparent multifariousness and complexity, it may suffice to state, that, as regards vegetable food, wheat and almost all the esculent grains consist principally of starch and gluten; that the same ingredients are found in many fruits and roots; that sugar, gum, or a relation of gum which is called *vegetable jelly*, together with minute traces of aromatic principles which give flavour, and more or less abundance of water and of vegetable acids, are the chief component parts of apples, pears, peaches, currants, gooseberries, and all analogous tribes of fruits; a very few also contain oil. Then, as regards animal food, the muscular parts of various animals closely resemble each other in composition and nutritive power; in some cases texture merely, and in others minute additions of foreign matters, confer upon them their relative digestibilities, and their different aspects and flavours: albumen or fibrin, and gelatine, small proportions of saline bodies, and a large quantity of water are found in them all.

It often happens that the truly nutritious part of food is so combined with or protected by indigestible matters, as to escape the sol-

vent powers of the stomach, unless previously prepared and modified by various chemical and mechanical agents. Indurated woody fibre, for instance, or *lignin*, will often resist the joint action of the stomach and bowels, and pass through the alimentary canal with scarcely any alteration. The husks of many seeds and fruits are composed almost exclusively of this material. This is the case with the kernels of the apple, pear, &c.; the seeds of the currant, gooseberry, melon, and so on; the skin or husk of peas, beans, &c., and of wheat, barley, and oats; so that unless this woody part is either broken down by the teeth, or previously removed, the food which it envelopes is protected from the solvent action of the secretions of the stomach. This is in some respects a wise and curious provision in nature; for birds in this way become the carriers of seeds, which pass through them not only undigested but even retaining their vegetative powers; and in this way uninhabited and sterile portions of the globe may gradually become clothed with verdure, and shrubs and trees. Bones are highly nutritive; but unless broken into very small fragments by the masticatory powers of the animals which eat them, they cannot be digested. In reference, however, to the food of man, much of its digestibility and nutritious power is referable to the important chemical operations, preparatory to its use, which are carried on in the kitchen: in other words, cookery is essentially a chemical art; and substances totally unfit in their raw state for reception into the stomach, are rendered palatable, digestible, and nutritious, by the skill of the cook. And here salt, and a variety of *condiments*, as they are called, and which are aromatic and stimulant substances chiefly of vegetable origin, play an important part: nor must the mere effect of heat be overlooked, for it is most important. Meat, by proper boiling and roasting, is not only softened in its fibre, but new substances are generated in it. Among these a peculiar extractive matter, and *osmazome*, or the principle which gives an agreeable flavour and odour to dressed meat, are especially recognised. Nor are the changes which vegetables suffer under the influence of heat less obvious.

There is another important point in the history of our food, namely, its *ultimate composition*. We have spoken of starch, sugar, gum, albumen, and other substances, as the *proximate* principles upon which we live; but what is the *ultimate* constitution of these secondary products—what are their true *elements*? It is curious that four *elements* only are principally concerned in the production of our food. These are carbon, hydrogen, oxygen, and nitrogen; and of these the bulk of our food is composed: but sulphur, phosphorus, lime, iron, and several other substances must also be present in it. Among vegetable substances gluten (including vegetable albumen) is the only one which abounds in nitrogen; gum, sugar, starch, and the rest are constituted of carbon, hydrogen,

and oxygen only; and what is very remarkable is, that in all these important principles, and also in lignin, the oxygen and hydrogen bear to each other the same relative proportions as in water, so that they may be figuratively described as compounds of *charcoal* and *water*. Now there are two very curious points in reference to that part of the chemical history of our food which has been adverted to: the one is, that no animal can subsist for any length of time upon food which is destitute of nitrogen; and the other, that a certain mixture of different kinds of food is absolutely essential. An animal fed *exclusively* on starch, or sugar, or albumen, or jelly, soon begins to suffer in health; peculiar diseases make their appearance, and his existence is painful and brief; but mix these together, and occasionally modify their proportions, and he then thrives and fattens. Magendie's experiments on this subject, together with those of Tiedemann and Gmelin, well illustrate this fact. Thus, geese fed upon gum died on the 16th day, those fed upon starch on the 24th, and those fed on boiled white of egg on the 46th; in all these cases they dwindled away and died as if of starvation. Physiologists have also made similar experiments upon dogs and other animals with the same result.

Habit, as is well known, will do much in accustoming the stomach to particular kinds of food; many persons live exclusively, or almost so, on vegetable, others on animal matters, and particular kinds of diet are forced on the inhabitants of many regions of the globe; but, as far as we are concerned, a due mixture of vegetable and animal matter is not only most palatable, but most conducive to health. Nothing is fit for food which has not already undergone organisation; and *water*, though an essential part of the food of all animals, is obviously not in itself nutritious, though it performs the extremely important function of dissolving nutritive matter, so as to render it conveyable by the lacteals and other absorbents into the blood. No compound then of nitrogen, hydrogen, carbon, and oxygen, which can be formed artificially, can constitute food. Air, water, and charcoal, though involving the principal *elements* of our nutriment, are themselves unfit for our support; and it is only by passing through the hidden processes which are carried on in the vessels of living things, that they are so recombined and modified as to be rendered capable of supporting animal life. It is the vegetable world which commences this wonderful operation. Plants absorb their nutriment from the air and from the soil; they assimilate inorganic matter; they become the food of the graminivorous tribes, and from these man derives the great bulk of his animal food.

In speaking of the composition of food, that of *milk*, the most important of all food, must not be forgotten; in it nature has wonderfully provided a mixture which, though secreted by an animal, partakes also of the nature of vegetable food, and it presents a perfect analogy to

FOOL.

that combination of vegetable and animal matter which has been mentioned as most congenial to the palate and stomach. The caseine or curd of milk is a highly elaborated animal principle, abounding in nitrogen, yet, from its attenuated and soluble state, easy of digestion. A second principle of milk is what is termed *sugar of milk*; in composition and properties it resembles a vegetable product, and is intermediate between gum and sugar. The third component of milk is *butter*, partaking of the nature of vegetable oil and animal fat; there are also certain saline and other substances in small proportion; and all these matters are either dissolved or suspended in a large relative proportion of water.

I. Table showing the average quantity of nutritive matter in 1,000 parts of several varieties of animal and vegetable food.

Blood	215	Carrots	98
Beef	260	Turnips	42
Veal	250	Cabbage	78
Mutton	290	Beetroot	148
Pork	240	Strawberries	100
Brain	200	Pears	160
Chicken	270	Apples	170
Cod	210	Gooseberries	190
Haddock	180	Cherries	250
Sole	210	Plums	280
Bones	810	Apricots	280
Milk	72	Peaches	200
White of egg	140	Grapes	270
Wheat	950	Malon	80
Rice	880	Cucumber	25
Barley	920	Tamarind	340
Rye	792	Almonds	650
Oats	742	Morels	896
Potatoes	260		

The above table represents the relative proportion of solid digestible matter contained in 1,000 parts of the different articles of food which are enumerated. When blood, for instance, is evaporated to dryness, at a temperature not exceeding 212°, the residue amounts to 215 parts in 1,000, and may be regarded as almost entirely composed of digestible matters; it consists chiefly of albumen and fibrin with small proportions of other substances. The loss of weight in the different kinds of meat during their desiccation is almost wholly referable to water; and the dry residue composed of albumen, fibrin, gelatine, and traces of fat, and of saline matters, represents the true nutritive value. Upon an average, therefore, the nutritive matter in a pound of meat is not more than four ounces. This, however, only applies to raw meat; for when dressed a considerable portion of its constituent water is often dissipated. The nutritive matter of wheat is chiefly starch and gluten, and in this species of grain the gluten is in greater relative proportion to the starch than in barley, oats, or rye. In rice starch predominates. There can be little doubt that the great value of wheat as an article of food depends upon this excess of gluten, which is a nitrogenous substance, and has not inaptly been termed the *vegeto-animal principle*. In the esculent roots, such as carrots, beet, parsnips and turnips, sugar is a leading nutritive matter; and

FOOT

the common fruits contain sugar, gum, albuminous matter, and acids, together with a highly attenuated form of woody fibre, or lignin, which, in that state, is probably digestible.

The following table shows the relative proportions of the carbon, hydrogen, oxygen and nitrogen which have been above adverted to as constituting the nutritive part of food: their supposed functions in a physiological point of view will be noticed under the head NUTRITION.

II. Table showing the ultimate elementary composition of 1,000 parts of the following proximate principles of animal and vegetable food.

	Carbon	Hydrogen	Oxygen	Nitrogen
Albumen	516	76	288	150
Gelatin	483	80	276	161
Fat	780	122	96	
Curd of milk	609	73	116	203
Sugar of milk	454	61	485	
Gluten	567	78	220	145
Starch	438	62	500	
Gum	419	68	513	
Sugar	444	62	494	
Lignin	500	56	444	

Fool's Parsley. An umbelliferous plant, common in waste ground, and so called from its having sufficient resemblance to plain or uncured parsley to deceive ignorant persons. It is a poisonous plant, acting like hemlock upon the human system; and is easily known by the involuclers having each three leaflets, which are always placed next the circumference of the umbel. It is the *Æthusa Cynapium* of botanists. All risk of injury from such a plant may be avoided by using only the curled leaved variety of the true parsley.

Fools, Feast of. A festival anciently celebrated in almost every church and monastery of France on New Year's Day. It was equivalent to the Saturnalia among the Romans, whence indeed it is said to be derived. This festival received some modifications in the different districts where it was celebrated, and acquired various designations according to the various ceremonies of which it consisted. Thus it was termed *la fête des diacres seuls, des cornards, des innocents*, &c. Several bishops and councils attempted, though in vain, to abolish this festival; but at length about the fifteenth century it became less generally observed, and soon after fell into almost total disuse, though its characteristic absurdities are still maintained in the Carnival of the present times. For full details on the Feast of Fools, see the *Encyclopédie des Gens du Monde*, under the head 'Fous (Fête des).'

Foot (Ger. *fuss*, Gr. *πούς, ποδός*). A measure of length. As this term is employed in almost all languages as a linear measure, it has doubtless been derived from the length of the human foot. Though the denomination is the same, the measure itself varies considerably in different European countries. [MEASURES.]

Foot. In Prosody, a measure consisting of two, three, or four syllables, long, short, or long

FOOTINGS

and short. All the combinations of which these numbers are susceptible amount to twenty-eight; and such is accordingly the number of feet enumerated by Greek and Latin prosodists, according to the following table:—

—	Pyrrhic	—	Ditrocheus
—	Spondee	—	Diambus
—	Trochee	—	Choriambus
—	Iamb	—	Antispastus
—	Tribrachys	—	Ionicus a minore
—	Molossus	—	Ionicus a majore
—	Dactylus	—	Pæon primus
—	Anapest	—	Pæon secundus
—	Amphibrachys	—	Pæon tertius
—	Amphimacrus	—	Pæon quartus
—	Baccheus	—	Epitritus 1
—	Palimbaccheus	—	Epitritus 2
—	Proceleusmaticus	—	Epitritus 3
—	Dispondeus	—	Epitritus 4

But by rejecting those which are merely duplications of disyllabic feet (Proceleusmaticus, Dispondeus, Ditrocheus, and Diambus), the number is reduced to twenty-four; and by also striking off those which are compounds of disyllabic feet (Choriambus, Antispastus, two Ionics, four Pæons, and four Epitrites), the number of simple feet becomes twelve only. The foot Amphimacrus is also known as the *Cretic*. [RHYTHM.]

Footings. In Architecture, the spreading courses at the base or foundation of a wall, by which the weight of the superincumbent mass is distributed over a larger area.

Footnotes. In Printing, the notes at the bottom of a page, usually set in type two or more sizes smaller than that of the text.

Footprints. Under this title we may conveniently include all the curious markings and impressions made by animals of all kinds on sands or muddy films covering sands, and owing to some favourable combination of circumstances preserved and permanently retained. There are few beds of sandstone favourably situated for such phenomena that do not exhibit them in abundance; and the subject is one of great interest.

Anyone who will watch for a time the phenomena on a tidal shore, where sands abound and clays are not far off, will find how common and varied are the markings produced; and it is not difficult to see that, though in most cases they must be obliterated by the next tide, they may possibly now and then be preserved. That they have been often retained, is clear from the *footprints* hardened and fossilised. A little blown sand and a few favourable chances of tide and time and weather seem sufficient to render them permanent.

But the markings thus made are not easily understood; we rarely know animals by their footsteps, and it is still more difficult to know them by the casts of footprints. The mark is made on soft sand; a little marly film covers it and preserves it; this again is covered with sand, and the whole becomes sandstone; but where the thin film of marl once covered the sand, there will be found on the sandstone the cast of the impression originally made on the soft sand. So accurately is this the case, that not only are the pit marks made by a shower

FORCE

of rain visible in certain rocks, but the direction of the wind driving the drops aslant is indicated by the more sloping side of the east of the depression on the stone.

There is hardly a limit to the variety of these impressions. Besides those made out, many are too obscure to be even guessed at. Worm marks, and marks of soft animals of that class, which have perished entirely; scratchings of crustaceans also, lost beyond hope; and the marks of other invertebrata of which we cannot even guess at the class, are plentiful. Even the fins of fishes appear to have left their mark. But it is chiefly footprints, and trailings of the tails of reptiles, that have attracted attention. Of these, many are of gigantic size, and indicate animals of very singular proportions. Bones have also been discovered, which correspond remarkably with the indications from the footmarks. [LABYRINTHODON.]

Foramen (Lat. *an opening*). In Anatomy, a small opening. The *foramen ovale* is an opening between the two auricles of the heart of the fœtus, which closes at birth.

FORAMEN. In Botany, the opening that exists in the integuments of every ovule.

Foraminifera (Lat. *foramen, a hole, and fero, to carry*) or **Rhizopoda** (Gr. *ρίζα, a root, and ποδς, foot*). A class of *Acrita* or *Protozoa*, composed chiefly of microscopic organisms, of which *AMOEBA* [which see] may be taken as a type. In some the gelatinous *sacculi* substance of which they are composed developes a calcified shell, usually consisting of an aggregate of chambers, intercommunicating by minute apertures, whence the name *Foraminifera*. The last formed segment is usually distinguished by the very long, slender, pellucid, colourless, contractile filaments which have suggested the name *Rhizopoda* for the class. The minute-chambered shells of *Foraminifera* enter largely into the composition of all the sedimentary strata, especially in the chalk.

Force (Ital. *forza*, from Lat. *fortis, strong*). In Statics, synonymous with *pressure*. In Dynamics, force may be defined as that which produces or changes motion. Forces are measured by the velocities which they can impart in a given time to given masses of matter upon which they act incessantly. In accordance with experiment, it is assumed that the force necessary to impart to a given mass a given velocity, or alteration of velocity, in the unit of time, is proportional to the mass as well as to the acceleration to be produced; the unit of force, therefore, is that which is capable, by continuous action throughout the unit of time, of imparting to the unit of mass the unit of velocity. The force which acting upon the unit of mass would impart to the latter the same acceleration as that which a given body receives, is usually called the *accelerating force* acting on the body. Thus since at the earth's surface all bodies acquire, in every second, an acceleration of velocity amounting to 30·19 feet, we say that the accelerating force of gravity $g=30·19$. The product of this

FORTIFICATION

fact, the regular bastions only form counter-guards. It was from a desire to take advantage of these tower bastions, which he found already existing at Landau when called upon to fortify that place, that he was led to adopt the system in question. Vauban's third system does not differ in any material respect from the second.

He increased the size of the ravelin, and gave it a redoubt.

The tower bastions were likewise made larger, and the cur-

tain which united them was broken inwards, so as to form two small flanks underneath; while casemates for cannon were constructed, to co-operate with those of the tower bastions in the defence of the ditch. In Vauban's first system the ravelin is much too small, the defects of which are: (1) that the besieger can establish himself along the glacis close to the covered way in front of the bastion, as well as along the glacis of the ravelin, and so needs not to capture the ravelin at all; and (2) that the shoulders of the bastion are not sufficiently covered by the ravelin. In the later systems these defects were remedied by advancing the salient of the ravelin about thirty or forty yards, and directing the faces on points thirty-two yards instead of eleven yards from the shoulder of the bastion. The addition of the redoubt in the ravelin tends also to prolong the defence.

Coehorn's System.—Contemporary with Vauban was the baron de Coehorn, director-general of the fortifications of the United Provinces of Holland. His methods are only applicable in low swampy countries, like Holland. By covering and flanking his works more effectually than had previously been done; by depriving the assailant of the room necessary for erecting his batteries; by making the ditches in front of the exterior envelopes wet, but those in rear of them, and between them and the main works, dry; thus providing a safe retreat for the defenders, and enabling them to form up conveniently to resist the enemy after he had crossed the wet ditches; and by keeping those parts of the works in which the besieger would have to make his lodgements, at such a level that he would come to water after digging a few inches deep, Coehorn endeavoured to apply the principles of the Italian bastioned system to the peculiar positions of his native land: extending and modifying these principles with great talent and success. An idea of his methods may be formed from the annexed figure, which represents his first system. It

will be perceived that there is an inner and an outer bastion and ravelin. The main ditch is swept by three flanks, the two lower ones being protected from all but direct fire by the *orillons*, which are casemated buildings placed at the shoulders of the bastions. The ditches are wider and shallower than in previous systems. Coehorn added redoubts *a c* in the covered way in the re-entering places of arms. Coehorn's principles

have been adopted in the construction of the fortresses of Nimègue, Breda, Mannheim, Namur, and Bergen-op-Zoom.

Cormontaigne's System.—The methods of Vauban were improved in many essential respects by Cormontaigne, a French officer of engineers, who died in 1760.

In the system which he adopted,

and which is here represented, the faces of the bastion are made longer than in Vauban's methods, and the flanks are placed at right angles with the faces of the opposite bastions. The enlargement of the bastion renders it capable of containing interior retrenchments; and the flanks, though shortened, are better covered. His ravelins are also constructed on a larger base, and contain a larger redoubt, from which the besiegers can keep up a reverse fire on breaches made in the collateral bastions; so that the assault upon the latter becomes impracticable until the ravelin and its redoubt are both captured. The communications round the extremities of the traverses of the covered way are arranged in a zigzag line; so that the passage round the extremity of one traverse is defended by the fire of another in its rear, and the advance of the assailants along the covered way thereby checked. Cormontaigne effected decided improvements by introducing redoubts into the covered way, thus giving a safe retreat to its defenders; and by giving flanks to the redoubt of the ravelin, but not to the ravelin itself, the faces of which, extending straight down to the main ditch, are better able to cover the shoulders of the bastions than those in Vauban's systems. One great defect in this system is that the ditch of the redoubt of the ravelin is not flanked properly from the enceinte.

Modern French System.—The annexed figure

represents what is called the *modern French system*: it varies but little from that of Cormontaigne. The ravelin is made to cover the shoulder of the bastion more effectually by a greater projection and wider base, and its faces are retrenched by *coupures* or cuts through the rampart, perpendicular to the faces of the bastion, which prevent the enemy from taking the redoubt in the re-entering place of arms without first possessing himself of the redoubt in the ravelin. The ditch of the redoubt of the ravelin receives flank defence from the faces of the bastion. Great attention has wisely been bestowed to make the communications for the defenders, between the different parts, safe and easy; that across the main ditch from the redoubt of the ravelin to the tenaille is covered

FORTIFICATION

by a *double caponier*, i.e. a parapet of earth on each side sloped off at the top like a glacis. The face of the bastion is protected from being breached through the ditch of the ravelin, by a traverse or mask of earth.

Among modern writers and engineers, Carnot advocates a detached escarp wall loopholed; a flat slope of earth, to allow the defenders to make sorties readily, in lieu of the ordinary counterscarp; a much more liberal use of vertical fire from mortars; and the adoption of bombproof casemated batteries. Dufour, directing his attention chiefly to preventing the outworks from being *enfiladed* by *ricochet* fire, raised the salients into *cavaliers* and *bonnettes*, to intercept this fire. Choumara suggested widening the ditch, and placing in it an interior *glacis* high enough to cover the escarp and sloped off to the foot of the counterscarp; and the formation of high traverses against ricochet fire at various parts, some of them being converted into cavalier batteries. Haxo as well as Choumara advocated the principle that the trace of the parapets need not be parallel to that of the ditches, whereby the parapets may be traced so as to fire with the best effect, and the ditches so as to be most convenient and least exposed: he invented casemated batteries built on the ramparts, and covered on their tops, sides, and fronts with earth, which are known by his name. Bousmard projected his ravelin bodily forward to the foot of the glacis, and curved the faces of his works to *lessen* the effects of ricochet fire. Chassoloup lengthened the *lines of defence* and constructed the faces of his bastions partly on the *exterior side of the polygon*. Noiset suggested the modifications and improvements contained in the *modern French system*.

All the systems above enumerated, however much they may differ in details, agree in their principal features, and present the same general outline. They may be all included under the name of the *bastion system*.

Polygonal or German System.—While the French in modern times have chiefly applied themselves to improving the bastion trace, the Germans, acting on the suggestions of Montalembert (to suppress the flanks and curtain, and allow the faces of the bastions to be produced inwards till they met), have heartily embraced the principle of what is termed the *polygonal system*—the enceinte being constructed either actually on the lines of the surrounding polygon or close to them; and both in theory and practice, they have carried it to great appa-

ral. The following is a description of one of the varieties of the polygonal system. The main ditch is flanked from the centre of each front by a *caponier* C, or arrangement of casemates in one or two tiers; as the guns in these would fire grape and case shot, the length of the *lines of defence* CA, CB, or distance from the caponier to the salients, may be about 300 yards; therefore the average length of the front or side of the polygon will be 600 yards. The front is slightly indented, to allow of the salient of the caponier being flanked from casemates in the indents HH. If the great central caponiers are built for two tiers of guns, it is plain that they can oppose two guns (or even three if the flat roof is armed) to every one the besieger can place in counter battery; and if this caponier be protected from serious injury from distant fire, it is evident that it will present an obstacle of the most formidable nature at the most critical period of a siege. To diminish as far as possible the space upon which the besieger would construct these counter batteries, the ditches at the salients are only twenty to twenty-five yards wide, gradually increasing in width towards the caponier, the counterscarp being traced to the ends of its sides, which are forty yards in front of the exterior side. Ten yards in front of the caponier is a casemated redoubt D, and ten yards in front of this is the ravelin E, which projects until its salient is 60°, i.e. as far as possible compatible with strength. The ditch of the ravelin is flanked by redoubts FF, which have earth raised on their tops to screen the entrance from fire down this ditch.

The *re-entering places of arms* have casemated redoubts GG in them. The caponiers may be placed at alternate angles of the polygon instead of at the centre of a front, and the lengths of the fronts may be reduced at pleasure; which is not the case with bastioned systems; one of its great merits is, therefore, its applicability to irregular sites.

The polygonal principle is eminently suited for small detached forts, many of which are now being constructed round our dockyards.

Attack of Fortresses.—Since the introduction of enfilade ricochet fire, the reduction of a bastioned fortress has proved such a certainty, when the attack is adequately and properly conducted, that the number of days required may be calculated beforehand with tolerable accuracy. The besieger having *invested* or surrounded the fortress, and cut off all means of ingress or egress, makes his *reconnaissance* or critical examination of the position: having selected the most favourable point of attack, he prepares his project of attack; he then makes

rent perfection. But as no fortress constructed on this system has stood the test of a siege, its advantages and defects are as yet only theoretic-

FORTIFICATION

his *first parallel* or trench, in which his *guards* of the *tranches* are placed to protect the men in the batteries, which are next constructed. The object of these is to reduce the fire of the place sufficiently to allow of the approaches being pushed forward in zigzags which afford secure communication to the front; other parallels are then constructed; and so on until the covered way is reached, the outworks breached and captured, and upon them batteries are constructed to breach the enceinte and silence its flanking fire; the assault is then made or the garrison capitulates. In the attack of a polygonal fortress, it remains to be proved whether or not the besieger will be able sufficiently to silence the reserved flanking fire of the main ditch, to be enabled to cross it. It also remains to be seen what will be the effect of rifled guns on the attack and defence: there can be little doubt that the first batteries and parallels must be commenced farther from the fortress, and that consequently the duration of the siege will be extended.

Defence of Fortresses.—An active defender will greatly delay and interrupt the siege operations of the besieger, by artillery fire and by sorties at night; and he will take timely heed to retrench those parts of the enceinte liable to be breached; but besides these and other obvious operations, he will place his guns as far as possible behind iron embrasures, and under bombproof covers, composed of timber supporting five or six feet of earth, called *blinded batteries*. No fortress can be said to be perfect in its defensive arrangements which has not a well-devised system of *countermine*s, placed under its most advanced glacis for a distance to the front of sixty or seventy yards; the galleries or vaulted underground passages (by means of which positions for the charges are reached) are placed near enough together—about twenty-five yards—to prevent the besieger passing between them without being heard; but this interval most probably will have to be reduced, as boring machines are being introduced instead of picks and shovels.

Although it is considered that the besieger, having unlimited resources at command, and being able to restore his damaged galleries, which the defender cannot, must eventually win in this subterranean warfare; still the delay to the besieger of nearly a month might be of the greatest importance in its effect on the campaign, and might lead to the relief of the fortress.

Field Fortification.—Field fortification is the art of constructing all kinds of temporary works for assisting the operations of an army in the field, and enabling it to maintain a position against a superior force. In the disposition and construction of such works, the engineer must have regard to the nature of the locality, and endeavour to turn to the best account all its natural advantages, as well as the buildings, enclosures, &c., which may be found on it; and there is no part of his art in which talent and skill are so requisite, or in which he

must rely so exclusively on the resources of his own judgment. On account of the endless varieties and accidents of the ground on which he has to act, the observance of fixed rules is, indeed, impracticable: nevertheless, there are certain general maxims which apply to the construction of fortifications of all kinds, whether temporary or permanent, and which must be observed in all his operations. For example, works constructed to flank others must not be at so great a distance as to be beyond the effective range of musketry: the angles of defence should be nearly right angles, and the salient angles as obtuse as possible. The general nature of defensive works is also the same in all cases, namely, a ditch and a parapet; though, as the pickaxe and the spade are the only implements which an army in the field can carry about with it, the depth and width of the ditch and the height of the parapet are in field works necessarily limited to what can be effected by these simple means.

Field works are usually divided into three classes: 1. Works open at the gorge; 2. Works enclosed all round; and 3. Lines either continued or with intervals. To the first class belong *redans*, single and double, and *lunettes*; to the second, *redoubts*, *star forts*, and *bastioned forts*; and to the third, lines of various kinds for defending a position. The *redan* is the simplest of all works, consisting merely of two lines, A B and A C, forming an angle with each other.

It is only employed for such purposes as defending the avenues of a village, bridge, or defile. The length given to it is usually about fifty yards. When the redan is thrown out in front of other works, it is called a *flèche*, or arrow. *Lunettes* are also applied for similar purposes, and are formed by adding two parallel faces, B D and C E, to the redan, at the extremities of its open flanks. The *double redan*, or *brevet de puits*, consists of two faces, A B and C D; and two flanks, A E and C E, usually shorter than the faces, and affording a reciprocal defence to each other.

There-entering angle at E should be a right angle: if it is less, the two flanks are in danger of being struck by each other's fire; and if it is much greater than a right angle, the defence will be weakened; for it is found by experience that soldiers placed behind a screen invariably fire straight before them, or at right angles to the screen. When a greater extent of front is to be fortified, the lines are disposed in the form of bastions or tenailles.

Redoubts are works closed on all sides, of a polygonal figure, usually a square. An opening is left in one of the sides, for communication with the exterior, and a traverse is thrown up within for protecting it. As the work is without flanks, the ditches are left without defence, unless supplied by two rows of stockades placed the ditch. Stockades are formed by firmly planting stout timbers, touching each other, in the ground, and loopholing them: a

FORUM

roof may be formed by placing timbers from one row to the other and covering them with earth. Counterscarp galleries may also be employed for flanking such ditches. The angles are sometimes rounded, or cut off, in order that a fire may be maintained on an assailant advancing in the direction of the diagonal.

Star forts are enclosed works constructed upon an equilateral triangle or a square. In the former case they have six points, in the latter eight. When constructed

on a square, each of the sides (which may be about ninety yards long) is divided into three equal parts, and on the middle part an equilateral triangle is constructed, which gives the trace of the figure. The object of this work is to remedy the defects of the redoubt by flanking the angles of the square.

Bastioned forts are constructed in the field on the same principles as in permanent works;

the distance A B, or exterior side of the polygon, should not exceed the range of musketry. They are employed only in fortifying important positions, and require accordingly to be constructed in a more solid manner than

other works of a temporary nature.

The last class of field-works comprehends *lines* of various descriptions. *Continued lines* are constructed to enclose a front, or connect principal works with one another by a continued parapet. They are constructed, according to circumstances, with redans, tenailles, or bastions, placed at intervals. From the descriptions given above, the different forms of the *redan line*, *tenaille line*, and *bastion line* will be readily conceived. Sometimes they are formed of a succession of faces and flanks at right angles. In

this case they are called *indented lines*. The flanks are about a fourth of the length of the faces, and afford a defence to the ditches. Lines with intervals consist of isolated works, as redans or redoubts, placed at intervals so as to afford one another a mutual defence.

Besides the works now enumerated, various expedients are resorted to in order to prevent, or at least to render more difficult, the approaches of an enemy. Among these are *palisades*, *abatis*, *trous-de-loup*, *chevaux-de-frise*, *crows' feet*, &c.

The principal authors on Fortification besides those mentioned above are Errard, Stevinus, Antoine de Ville, De Pagan, Mallet, Belidor, Blondel, Bissot, Mousé, &c. [IRON ARMOUR PLATE.]

Forum (Lat.). In Roman Antiquities, an open space before any buildings, especially before sepulchres. The fora of the Romans were large open squares, surrounded by temples, houses, basilicas, or porticoes; they served

FOSSORIAL

as market places, as well as for public meetings of the citizens, and for the administration of justice. The forum was also, in later times, used for the shows of gladiators. There were in Rome fourteen fora for the sale of goods, provisions and merchandise; these were thence called *fora venalia*. There were three others for civil and judicial proceedings, called *fora civilia* and *judicialia*; one of these was the Forum of Trajan, of which the column erected in memory of his victories over the Dacians was the principal ornament. [AGORA.]

Fossa (Lat. *a trench*). In Zoology, this term is applied to certain depressions on the external surface; generally the seat of cutaneous glands, as the *lacrymal fossa* in deer and antelopes.

Fossa. [VALLUM.]

Fossa Ovalis. A depression in the right auricle of the heart, which in the fetal state opened into the left auricle, forming the *foramen ovale*.

Fosse (Fr.). [DITCH.]

Fossil (Lat. *fossilis*, from *fodio*, *I dig*). Literally, anything dug out of the earth. The term is now chiefly confined to organic remains.

Fossil Farina. A soft carbonate of lime.

Fossiliferous Rocks. Rocks containing fossils or organic remains. Rocks are thus designated which have been found in any part to contain fossils, although in some places they may not exhibit them. Thus, many sandstones are in part barren of organic remains; but as such remains are found in some sandstones, the latter belong to the fossiliferous series. Mechanical rocks without any fossils are not perhaps to be found in any country. Even slates and greatly metamorphosed limestones almost always contain some proof of their having originated in the vicinity of life, and hardly any sandstones not actually quartzites can be regarded as without fossils. Gneiss has lately been recognised as fossiliferous. The term is therefore better explained by negative than positive expressions. Granites, lava, basalt, and mica schist have never yet been found to show organic marks even of the faintest kind, and they are for the present therefore excluded from the list of fossiliferous rocks; everything else is included.

Fossorial (Lat. *diggers*). An extensive group of Aculeate Hymenopterous insects, most of the species of which are organised for excavating cells in earth or wood, in which they bury other insects in a wounded and feeble state, and at the same time deposit their eggs; so that the larvae, when hatched, find a store of food prepared for their sustenance. The Fossorial Hymenoptera are solitary in their habits; and some species, which have not the requisite structure of the legs for burrowing, are parasitic, and, like the cuckoo among birds, lay their eggs in the nests of other species, at whose expense the young are reared.

Fossorial. In Zoology, animals which dig their retreats and seek their food in the earth are so called. The locomotive extremities, which are organised for burrowing, as those

FOSSULATE

of the mole, or mole-cricket, are called *pedes fossarii*.

Fossulate (Lat. fossa, a trench). When a surface presents one or more somewhat long and narrow depressions.

Fother. A weight of lead containing eight pugs. At the mines it is equal to twenty-two and a half hundredweight, but with the plumbers in London it is nineteen and a half hundred-weight.

Fougass (Fr. fougasse). In Fortification, a small mine, from six to twelve feet underground. It sometimes consists of one or more loaded shells, sometimes of a charge of powder covered with small stones.

Foul. The term applied to the wind when contrary; also to the bottom when uneven and rocky. [ANCHOR; FALL; HAWSE.]

Foundation (Lat. fundatio, though only used in Latin in an architectural sense). A term applied to such permanent institutions as were intended at the time of their creation to serve some purpose of utility or charity, or to perpetuate some real or supposed service to the community or an individual. Thus some of these institutions are devoted to the cause of education general or special, as the endowments bestowed on students, teachers, and professors in universities, where the benefaction is intended either to stimulate study, or to aid those who are imparting what they have learnt, by affording comparative leisure for the occupation which they follow. Some are of a charitable character; as, for instance, the endowment of hospitals, schools, asylums, and almshouses, where occasional distress or unavoidable poverty furnish a plea for taking the objects of charity out of the condition into which the ordinary operation of social forces in the competition for the means of life has put them. Or, again, a foundation may be created for the purpose of giving facilities for the supply of undefined but probable services, as those which are devoted to the maintenance of purely scientific investigation—for instance, an endowment to an observatory. And lastly, some may have a distinctly religious object. Thus the college of All Souls in Oxford owes its existence to a benefaction of Archbishop Chichele, who intended to supply a perpetual charity, in which prayers and similar services should be duly and regularly offered for the souls of those who had perished in the various wars with France.

The privilege of devoting a portion or the whole of one's substance to these and similar purposes has been regarded with great jealousy during the whole of the legal history of England. Grants of land for the endowment of charitable foundations are generally prohibited under the mortmain Acts, though the suspension of these Acts in favour of any particular institution is left to the discretion of the crown, and forms the sole relic of that portion of the prerogative which occupies so large a space in the constitutional history of this country, under the name of the *non obstante* clause or dispensing power.

FOUNDATION

It does not appear, however, that the motives which led to this hostility have ever been very clearly expressed, or referred to any rational principle. The preamble of the last mortmain Act assigns as a reason for its enactments the danger which may arise from the possible disinheritance of lawful heirs, an inconvenience which is not very obvious where there happens, as is generally the case, to be either no heir at all, or no heir sufficiently near to stimulate the supposed duty of devising one's estate to relations never heard of or never cared for.

Foundations or endowments have an economical significance, and must be governed and regulated with a view to public utility. It is manifestly only by a consideration that tantamount or greater advantages are secured to mankind by such a determination, that persons can be permitted to bind posterity in the appropriation of a particular part of the soil of any country to permanent special purposes. No right accorded to a testator, by which he can after death exercise a control over the volition of the living, can be defended on abstract principles, but only on the entirely-*a posteriori* considerations of probable public benefit; and if it be shown that the right exercised is mischievous to society, every existing generation may justly rescind the power, and resume the impropriation. And there can be no case in which this power of ultimately revising the terms of a gift or grant for future or permanent purposes, and of annulling it if it should appear inexpedient in its effects, is more inalienable than when the gift is made in something of absolutely limited quantity and of great necessity, such as land. To maintain that grants in perpetuity for special purposes are so sacred as to be taken out of the possibility of future alteration or resumption, is to argue that the dead may always bind the living, that those who have long since quitted the business of human life may continue to control the action of those who are constrained by all considerations of duty and prudence to make the best use of the materials before them in their own generation.

There is, however, an economical defence for some endowments, even in perpetuity. In the ordinary course of society, services proffered, received, or exchanged, have an immediately intelligible value. They are produced, and their production is sustained by demand; and if individuals continually interpreting their worth, continually desire them, the supply is forthcoming sooner or later, at home or from abroad, and any indirect stimulus is not only unnecessary, but mischievous to all parties. Not so, however, in two cases: one, that in which the service is of great and demonstrable value, but where the value is only remotely or obscurely applicable to the individual; the other, where the demand is exceedingly urgent, but the capacity for securing the supply is not and could not be voluntarily, rapidly, or even ultimately possessed by the person deriving the advantage in question.

FOUNDATION

Under the first of these fall such endowments as are made for educational purposes. We all know how much economical value is added to labour when it is educated. But to wait till those who are ignorant, vicious, or dishonest wish to be taught, would be the silliest act of the laziest optimism. Of course the assertion of this principle does not involve the assertion of its details, or determine that this or that method is to be adopted in imparting the education needed; but it does imply that when the morality of society and the conscientiousness of individuals are far more advanced than at present, the supplementary aids of primary education may be abandoned. Similar reasonings apply to the higher branches of study and thought. Every moral and material improvement, every political and economical reform, has been achieved by theory at the expense of experience. It was out of the comparative leisure afforded by an endowment that Adam Smith announced those theories which, with some corrections and additions, are now recognised as equivalent to social laws, but which directly contravened experience in the first instance. It was in complete opposition to experience that Galileo developed the true solar system, and made it possible to transfer the study of the heavens from the dreams of the astrologer to the practical labours of the scientific navigator. There is certainly no department of human thought which has not been illustrated by patient speculative enquiry, and as yet nothing has aided such enquiry so much as the existence of endowed foundations.

In the second place, foundations are of the greatest importance where the demand is urgent, necessary, and natural, but the capacity to secure the supply is wanting. Such are hospitals and asylums. The services of experienced physicians and surgeons are necessarily costly, and in ordinary cases wholly beyond the means of many members of the community. The most frequent of the cases, too, in which the service is required are unforeseen, and therefore cannot be provided for, at least in any great degree. The accident which may deprive a man and his family of his bread, the sickness which may prostrate his energies, the disease which may paralyse his mind, are contingencies which fall within the calculations of a statistical average, but cannot be said to be justly or necessarily present to an individual labourer. The charity, therefore, which provides aid or refuge from these calamities, is wholesome, expedient and just, and could not be discouraged without a serious public detriment.

The same reasoning applies to endowments for the education of orphans and children whose parents are unable to support them. The inability may be the vice of the parent, but it cannot be the sin of the child. Hence, if such institutions can be preserved from abuse, and if they are found to be always necessary, society may justly, both for its own sake and for the sake of those who receive the bounty or aid,

FOUNDING

interfere to lighten undeserved and helpless suffering.

Foundations. In Architecture, the lower part of a wall, on which the weight of the insistent mass is raised, and always of a much greater thickness than such insistent wall. The practice of the ancients of laying the foundations on concrete, composed of hydraulic or other lime (as they may be required to resist the effects of water, or otherwise) mixed with coarse gravel, has been lately revived with considerable success. When concrete is well made, it is adapted to this purpose. Unfortunately in England the proper mode of using lime is so little understood, that the concrete generally employed is in fact nothing more than sand, with a small quantity of cementitious material. Sand is, however, a good foundation provided it be prevented from spreading laterally.

Founding or Foundry. The building in which various metals are cast into moulds or shapes. Such of the details of the processes carried on in the respective metal foundries as are consistent with the plan of this work, will be found under the heads of the metals to which they refer. The furnaces used in fusing and founding metals are variously constructed, according to the nature of the metal and the quantity to be operated upon; and frequently furnaces of different constructions are employed in the same foundry. The wind furnace, blast furnace, and reverberatory furnace, are the forms which are most generally employed. The wind furnace is either square or circular, and varies in dimensions, according to the size of the crucibles which it is intended to contain, and which are placed upon proper supports resting generally upon the bars or grating of the furnace. It has three apertures; one above, for the purpose of introducing the crucible and fuel, and which is usually closed by a fire tile or brick; another below, for the purpose of admitting the air, so as to pass through the grate and fuel, and up the chimney; and the third communicating with the chimney, which should be lofty and supplied with a damper, for the purpose of regulating the draught of air through the fireplace, and consequently also the heat produced.

The blast furnace differs from the preceding in having no grating, and in the air being supplied by a bellows or blowing machine. The construction of these furnaces is much varied, according to circumstances; but the largest and most perfect are those employed in the iron works.

The reverberatory furnace is so constructed, that the flame and hot air from the fireplace are directed into a separate cavity intermediate between it and the chimney. In this cavity, commonly called the *hearth*, the materials to be fused are placed; and there is an aperture connected with it by which the fused metal is suffered to run out, or through which it may be removed in ladles for the purpose of supplying the moulds.

The materials of which the moulds are

FOUNDLING HOSPITALS

formed are very various. In some cases, as in stereotype founding, they consist of plaster of Paris; in bronze works for figures and statues, they are made of a mixture of plaster of Paris, sand, and brickdust, and require the utmost skill and care in their preparation. Iron is usually cast in sand; brass and other metals in clay; and very frequently the moulds are made of cast iron.

Foundling Hospitals. In those ancient nations with the details of whose social life we are acquainted, the practice of exposing newborn infants seems to have been, as it is at this day in China, a species of legitimate infanticide. Neither Plato nor Aristotle, nor in general any political writers of antiquity, condemn it; they merely profess to lay down rules for the preservation of the healthier and stronger, at the expense of the more weakly. Among the Greeks a more tender mother chose the market-place, or some temple for the exposure of her child, in order to have the chance of some charitable hand succouring it: if its death was desired, it was abandoned in solitary places; and their dramas and romances are full of narratives in which this custom forms the foundation of the interest. Thebes, in republican Greece, is the only state in which the exposure of children is known to have been forbidden by law. The practice of exposure was common in republican Rome: the law is doubtful. The street called Velabrum (Juvenal, *Sat.* vi.) and the column called Lactaria (from this circumstance, according to some antiquaries) were places usually selected for the purpose. Abandoned children were declared by law to be the slaves or absolute property of those by whom they were brought up; and several were saved from death, not from human motives, but that their foster-fathers might, by mutilating their persons, and exhibiting them in the streets, derive an infamous livelihood from the alms given them by the passengers. At length the progress of Christianity put an end to these disgusting enormities. The exposure of children was made a punishable offence in A.D. 374; and their slavery was abolished by an edict of Justinian in 530.

Infanticide has most properly been prosecuted with the utmost rigour, and made a capital offence in almost all modern countries. But it was early supposed that were the exposure or abandonment of children wholly prohibited, there would, despite of all that could be done to prevent it, be a great deal of infanticide. In consequence of the prevalence of this feeling, it has been customary in the Christian world, from a very remote period, to connive at the abandonment of children, and to provide means for the support of those that might be abandoned; and hence the origin of foundling hospitals.

The first distinct trace of an express foundation for foundlings is at Milan in 787. In 1070 the order of Brothers of the Holy Ghost was established with the express of taking care of sick, orphans, and foundlings.

After that time this species of foundations rapidly multiplied in every part of Europe. But while private beneficence was thus exerted in their behalf, the church, which in the earlier period had undertaken the general care of them, seems by degrees to have thrown on the community, in most European countries, the charge of nourishing such as were not received into any of the foundations. Traces of legal contests between the religious and civil establishments on this subject are to be found in the history of France through the whole sixteenth century. The uncertain state of the law rendered their preservation in that country extremely precarious. St. Vincent de Paul, in the seventeenth century, undertook their cause; and the foundation of the great Foundling Hospital of Paris, in 1670, is due to his efforts. In the provinces, and in most Catholic countries, and in those under the Greek Church, public charity took the same direction.

It has been customary in these establishments to receive all children brought to them, without enquiring whether they were the fruit of regular marriages or of illicit amours. It seems idle to deny that the multiplication of such establishments, by providing a ready method for disposing of children, must have hindered a few cases of infanticide; but the injury they have done to public morals, and the waste of human life which they have occasioned, are ten times greater evils than any they have obviated. Well-informed persons in this and other countries have long been aware of the pernicious tendency of foundling hospitals; and it is probable that at no very distant period they will be everywhere suppressed. In France the multiplication of these hospitals, and of exposure, has at last called the attention of the public to the frightful immorality, mortality, and expense which attend it. In 1680, ten years after its foundation, the great hospital at Paris admitted 890; in 1750, 4,000; in 1830, nearly 8,000. In all France there were nourished at the public expense, in 1784, 40,000 children; in 1809, 69,000; 1826, 118,000. The number in 1848 was 98,872, and it is still decreasing. It varies greatly in the different departments; being greatest in the north, centre, and south; least in the eastern departments bordering on Germany, and in the western, or Brittany, La Vendée, &c. The statistics of France plainly show that it is 'not poverty, but luxury, which produces exposures.' (Terme and Montaleon, *Histoire des Enfants Trouvés*.) The two great measures for reducing the burden which have lately been partially put in execution, are the suppression of the turning-boxes, or, in other words, rendering the abandonment public; and the removal of the new-born children into another department, which, it is said, always produces, when tried, a great reduction in the number of exposures. In Italy, Belgium, &c., similar institutions prevail, and a similar increase of burden has of late years been felt. It has, no doubt, been augmented by the improve-

ment which has taken place in the management of these unfortunate creatures. Formerly death soon relieved the institutions of their maintenance. Towards the end of the last century, 80 per cent. of the children are said to have died at Paris in a single year; 90 at Marseilles; 91 at Dublin. The mortality is now much diminished; though it is thought that in France nearly 60 per cent. still die in their first year. The whole number of children annually exposed is said to be, at St. Petersburg, about 45 per cent. of those born; Rome, 28; Lisbon, 26; Vienna, 23; Paris, 21. In England, Captain Thomas Coram is celebrated for his establishment of the Foundling Hospital in 1739. It was extremely popular at the time, and for many years was assisted by frequent votes of parliament. Similar institutions were projected in other parts of the country; but the enormous increase of abandonments, and the expense which they occasioned, produced such an alteration in public opinion, that the system of the foundling hospital was entirely altered; and, notwithstanding its name, it is now destined merely for the reception of orphans. Abandoned children in England become burdens to the parish in which they are found.

Fount or Font (Fr. *fonds*). The quantity of types of any particular sort in a printing office, whether it be great or small. Thus a small fount may consist of fifty or one hundred pounds weight, comprising the usual proportion of the various letters of the alphabet; and a large fount of thirty thousand or forty thousand pounds weight, or more. When the typesetter has not cast a proportionable number of each type, the letters required are called *imperfections*, as making the rest of the fount imperfect.

Fountain (Lat. *font*). By this term is designated any natural or artificial apparatus by means of which water springs up. In natural fountains the ascensional effort is produced by the hydrostatic pressure of the water itself; in artificial fountains it is produced either by the same pressure, or by that of compressed air, or sometimes by machinery.

Natural fountains have their origin as follows: The rain which falls from the atmosphere is absorbed in three different ways. One part of it collects in rills on the surface of the ground; this unite in streams or rivulets, which flowing into one another form rivers, and thus it is conveyed to the ocean. A second part is taken up in giving humidity to the soil, from which it is returned to the atmosphere by evaporation. A third portion descends into the earth, through soils of a spongy or porous nature, or through crevices and interstices in the strata, until it meets, frequently at a very considerable depth, with strata through which it cannot penetrate, and is then collected in subterraneous reservoirs. When confined in this manner, it is subject to the pressure of the water which fills the channels through which it has descended; and when this pressure is sufficient to overcome the resistance of the superincumbent mass of earth, the water

breaks through the superficial strata, and gushes forth in a spring. But if the strength of the superincumbent materials exceed the hydrostatic pressure, the water will remain stored up as it were in the subterraneous reservoir. Now if the ground above such a reservoir, or any channel communicating with it, be perforated, the water, having free access to the opening, will rise in it till it attains the level of the highest part of the channels from which it is supplied. If this level is above the surface of the ground, the water will have a tendency to rise; and when the ascensional force is considerable, it may by proper means be formed into a fountain. That subterraneous reservoirs formed in this manner exist in great abundance, and at great depths under the surface, we have sufficient evidence in the facility with which water may be obtained in almost all countries from *Artesian Wells*. [**ARTESIAN WELL**; **HYDRODYNAMICS**.]

Fountain of Hero. An ingenious hydraulic machine, of which the invention is ascribed to Hero of Alexandria, who lived about 160 years before our era. Its principle is the transmission of the pressure sustained by a body of water in one vessel to that in another by means of the elasticity of air. The essential parts of the apparatus consist of two close vessels, A and B, the first placed at some height above the other, and connected by a frame; and of three tubes or pipes, of which the first, *ab*, descends from a basin C to very near the bottom of the lower vessel B; the second, *cd*, rises from the summit of the vessel B to the top of A; the third, *ef*, rising from the lower part of A to some height above A, and forming the jet at *f*.

Conceive the vessel A to be filled with water, and B with air. In this disposition of the apparatus, let water be poured into the basin C; this will descend through the pipe *ab*, and gradually fill the vessel B. But as it rises in B the air in that vessel escapes through the pipe *cd*, and is compressed at the top of A, and, by its spring or elasticity, forces the water through the tube *ef*, and thus produces a jet at *f*, which will continue until the vessel A is nearly emptied, or B nearly filled. The force which produces the jet is equal to the pressure of a column of water, the height of which is equal to the difference of the levels of the water in C and B: according to this theory, therefore, the water should spout to a height above its level in A equal to that distance; but its friction against the walls of the tube *ef*, and the resistance to its ascent offered by the air, prevent more than a fraction of this height being attained.

The second figure represents the fountain of Hero in another form. An apparatus constructed on this principle is employed for draining the water from the mines of Schemnitz in Hungary.

FOURIER'S THEOREM

Fourier's Theorem. An important algebraical theorem discovered by Fourier at the commencement of the present century, though only published in 1831, after his death. Although theoretically inferior to *Sturm's Theorem*, it provides us with a convenient method of ascertaining the maximum number of real roots of an equation which lie between prescribed limits. It may be thus enunciated: The number of real roots of an equation $F(x)=0$ which lie between given limits α and β cannot exceed the difference between the variations in sign presented by the two series

$$F(\alpha), F'(\alpha), F''(\alpha), \dots, F^{(n)}(\alpha); \\ F(\beta), F'(\beta), F''(\beta), \dots, F^{(n)}(\beta).$$

The demonstration of this theorem, given in all text-books, is based upon the following two properties: 1. Whenever during its gradual increase, x passes through a root of $F(x)=0$, the series

$$F(x), F'(x), F''(x), \dots, F^{(n)}(x)$$

loses as many variations of sign as there are roots equal to that root. 2. The series never gains variations of sign when the derived functions vanish, and never loses them but in even numbers. It will be observed that when $\alpha=0$ the above series reduces itself to that of the coefficients of the given equation, taken in inverse order, and when $\beta=+\infty$ the series presents no variations of sign; so that for these two limits, Fourier's theorem coincides with DESCARTES' RULE OF SIGNS.

There is another theorem in the integral calculus, due to the same eminent mathematician, which must here be mentioned, inasmuch as it is also frequently referred to as *Fourier's Theorem*. According to it, any function $f(x)$ may be expressed in the form of a double integral, thus:

$$f(x) = \frac{1}{\pi} \int_0^\pi d\omega \int_{-\infty}^{\infty} \cos \omega(x-v) f(v) dv;$$

a formula of the greatest importance in pure and applied mathematics. For its demonstration, as well as its exact signification, we must refer the reader to De Morgan's *Differential and Integral Calculus*; to a very able paper by Prof. Boole in the *Transactions of the Royal Irish Academy*, vol. xxi.; or to Fourier's *Théorie de la Chaleur*, Paris 1822, in which the theorem originally appeared.

Fourierism. A system of political and social government has been so called from the name of its founder, or rather imaginer, Charles Fourier of Besançon. [SOCIALISM.]

Fourth. In Music, one of the harmonical intervals; so called as being the fourth in order of the natural or diatonic scale from the fundamental. The ratio of the vibrations of the two sounds producing the interval of the fourth is 3:4.

Fusel Oil or Fasel Oil (Gr. $\phi\alpha\varsigma$, *I produce*). An oil contained in corn-spirit and potato-spirit, which gives to those liquors a disagreeable taste and smell. When purified it constitutes the *amylis alcohol*, or hydrate of

FRACTION

oxide of amyle, of modern chemists; its formula is $C_{10}H_{21}O + H.O$. [AMYLE.]

Fovilla. In Botany, the matter contained within the grains of pollen.

Fowler's Mineral Solution. A solution of *arsenite of potassa* introduced into medicine by Dr. Fowler of Stafford, as a substitute for a similar preparation, sold as a quack medicine, under the name of *Tasteless Ague Drops*. The *Liquor Arsenicalis* of the Pharmacopœia is for the same purpose.

Fowling. The art of catching birds with nets, birdlime, decoys, or other devices. It is also used for taking birds with hawks, falcons, and other birds of prey; more properly called *falconry* and *hawking*.

Fox. [VULPES and CANIS.]

Fox. A particular kind of strand made of rope-yarns.

Foxglove. The *Digitalis purpurea*, a common indigenous plant, the leaves of which, when carefully dried and powdered, or made into a tincture or infusion, are used in medicine. In small and repeated doses it lowers the pulse in an extraordinary manner, and produces debility and fainting; combined with other remedies, it forms an ingredient in some powerful *diuretics*. [DIGITALIS.]

Fraction. In Arithmetic, one or more aliquot parts of unity. In order to form a precise idea of a fraction of any unit, we must consider the unit to be divided into a certain whole number of equal parts, of which parts we take one, two, three, &c. The expression of a fraction therefore necessarily involves two whole numbers; namely, one to denote the number of parts into which the unit is divided, and the other to express how many of these parts are to be taken to form the fraction. The first of these numbers is called the *denominator*, and the second the *numerator*, and the fraction is denoted by placing the numerator above the denominator with a line or bar between them. Thus *seven eighths* is represented by the symbol $\frac{7}{8}$.

A fraction may also be regarded as the quotient that arises from the division of its numerator by its denominator. For example, the expression *seven eighths*, or seven times the eighth part of unity, is identical with the expression *the eighth part of seven units*, or *seven divided by eight*.

From the above definitions of the numerator and denominator of a fraction, the following consequences result: 1. If, without altering the denominator of a fraction, we multiply or divide its numerator by any number, the new fraction will be so many times greater or less than the original fraction. 2. If, without altering the numerator, we multiply or divide the denominator of a fraction by any number, the new fraction will be so many times smaller in the former case, and so many times greater in the latter, than the original fraction. 3. The value of a fraction is not altered by multiplying or dividing both numerator and denominator by the same number. It is on these

three principles that the practical rules for the addition, subtraction, multiplication, and division of fractions are grounded.

A fraction whose numerator and denominator contain no common factor is said to be in its *lowest terms*. A *proper fraction* is one whose denominator exceeds its numerator; whose value, consequently, is less than unity. A fraction whose numerator exceeds its denominator, and which is consequently greater than unity, is said to be an *improper fraction*. Such a fraction may be expressed as a sum of a whole number and a proper fraction; thus, $\frac{10}{3} = 2 + \frac{4}{3}$. This result, written in the form $2\frac{4}{3}$, is called a *mixed number*. A fraction whose numerator and denominator consist of other fractions or mixed numbers is termed a *compound* or *complex fraction*, to distinguish it from the simple fraction to which it may always be reduced.

Thus $1 + \frac{4}{3}$ is a complex fraction equal to the simple improper fraction $\frac{7}{3}$ or to the mixed number $1\frac{4}{3}$. For one very important class of complex fractions, see CONTINUED FRACTION.

Fractions whose denominators are powers of 10 are termed *decimal fractions*, and are expressed by a different notation. [DECIMAL FRACTION.]

Fraction, Vanishing. An algebraical fraction which, under a certain hypothesis, assumes the indeterminate form $\frac{0}{0}$. Thus $\frac{x^2 - 1}{x - 1}$

is a vanishing fraction when $x = 1$. The true value of a vanishing fraction is the limit to which it approaches, as the hypothesis which causes the fraction to vanish is gradually approached. Thus, as x approaches the critical value 1 in the above example, the fraction approaches the limit 2. The general method of finding the true value of a vanishing fraction is to replace its numerator and denominator by their differential coefficients, and to substitute in the result the critical value of the variable; should the fraction thus derived be again a vanishing one, the operation must be repeated. Thus, for $x = 1$

$$\frac{a^x - a}{b^x - b} = \frac{a^x \log a}{b^x \log b} = \frac{a \log a}{b \log b}$$

Fractions, Partial. [FRACTIONAL FRACTIONS.]

Fracture (Lat. *fractura*, from *frango*, I break). In Mineralogy. When minerals are broken, they either exhibit a smooth regular surface, to which the term *cleavage* is generally applied; or they give an irregular or uneven surface, termed a *fracture*. Werner, who first employed this character in his description of minerals, divides their various fractures into compact, fibrous, radiated, and foliated. The terms *earthy*, *granular*, *uneven*, *hackly*, and *splintery*, the meanings of which will be sufficiently obvious, are employed by other mineralogists.

Fracture. In Surgery, this term is limited to broken bones. Such accidents are generally the result of external force; but it sometimes happens that the powerful action of certain

muscles may cause a fracture, as is frequently the case in regard to the *patella* or *knee-pan*. Fractures are distinguished by surgeons into *transverse*, *oblique* and *longitudinal*, depending upon the direction in which the bone is broken; and into *simple* and *compound*, dependent upon the circumstances with which the injury is accompanied. By *simple fracture* surgeons mean a suddenly formed breach in the continuity of one or more bones, without any external wound communicating internally with the fracture; by a *compound fracture* they signify the same sort of injury of a bone or bones, attended with a laceration of the integuments, which laceration may be produced by the protrusion of one or both ends of the fracture through the skin, or by a ball or other body which enters or otherwise wounds the soft parts at the same moment that it breaks the bone.

Frænum. [FRENUM.]

Fragaria (Lat. *fraga*, *strawberries*). The Strawberry plant forms a genus of *Rosaceæ* known by its ten-cleft calyx, its five petals, and its seeds inserted on a fleshy receptacle. This latter forms the fruit known as the Strawberry, one of the most grateful and wholesome of all our hardy fruits. The varieties of the Strawberry are very numerous, and come from several distinct species, the principal of which are *F. vesca*, *clatior*, *virginiana*, *grandiflora*, and *chilensis*.

Fragmentary Rocks. A geological term applied to rocks apparently composed of the agglutinated fragments of other rocks. *Breccia* and *conglomerates* are of this class.

Fraises (Fr.). In Fortification, a defensive obstacle formed by driving pointed stakes at a small angle with the horizon into the edge of the ditch of a work, &c.

Framboesia (Fr. *framboise*, a raspberry). The yaws; a disease endemic in the Antilles and some parts of Africa, which is attended by cuticular excrescences something like raspberries, which discharge a watery fluid. It is contagious, but not dangerous.

Framing. In Architecture, the rough timber work of a house, including floors, roofs, partitions, ceilings, and beams. Generally any pieces of wood fitted together with mortises and tenons are said to be framed together; as doors, sashes, sash-frames, &c.

Franc. A coin in use in France, equivalent to 9-69d. [MONEY.]

Franchise (Fr. from the Teutonic *frank*, free). In Law, a species of incorporeal hereditament, synonymous with liberty, which is defined, 'A royal privilege or branch of the king's prerogative, subsisting in the hands of a subject.' For an account of the nature of the *elective franchise*, see PARLIAMENT.

Franciscans. One of the four Mendicant Orders, founded by St. Francis of Assisi, in Umbria, in the year 1209. [ORDERS, MENDICANT.]

Francoaceæ (Franco, one of the genera). A natural order of hypogynous Exogens of the Ericol alliance, distinguished especially by their

FRANK

polypetalous flowers, their free stamens half of which are sterile and scale-like, and their tight-skinned seeds. The species of *Franseria* are regarded in Chili as cooling and sedative, and their roots dye black.

Frank. A privilege enjoyed by the members of both houses of parliament, some government offices, and certain public functionaries, of sending and receiving a certain number of letters *post free*; abolished Jan. 10, 1840. [POSTAGE.]

Frank Aleu. This word is still used in Lower Canada, and also in Guernsey and Jersey, to denote land acknowledging no feudal superior, and consequently not a *tenure*. [FEUDAL SYSTEM.]

Frankalmoin (from two Norman-French words, signifying *free alms*). In Law, a tenure by spiritual service, where an ecclesiastical corporation, sole or aggregate, holds land to them and their successors of some lord and his heirs in free and perpetual alms. Donations in frankalmoin are now out of use, as none but the king can make them; but they were expressly excepted from the operation of stat. 12 Ch. II. c. 24, which abolished military tenures.

Frankeniaceae (Frankenia, one of the genera). A small natural order of hypogynous Exogens, of the Violal alliance, chiefly remarkable for their polypetalous flowers, tubular furrowed calyx, and hypogynous clawed petals. They are chiefly natives of North Africa and Southern Europe, and are of little interest.

Frankincense (said to be so called from its liberal distribution of odour). The gum-resin *Olibanum*, which is the produce of the *Boswellia thurifera* or *seerrata*, and is imported from the Levant, bears the commercial name of *frankincense*. When it is burnt, or sprinkled upon hot coals, it exhales a very fragrant and diffusible odour.

Frankinite. A ferriferous oxide of zinc occurring in New Jersey, North America; named in honour of Dr. Franklin.

Frankpledge or **Freeborg** (Ger. *bürge*, *pledge*). A celebrated Anglo-Saxon usage, which appears to have been of two kinds. 1. That which may be termed *seigniorial frankpledge*, by which every lord (blaford) was rendered responsible for the appearance of his own men or dependants, when accused before justice in the hundred court; when, if the party absconded, the lord became liable to the king in the amount of the *were* or amercement for the offence. 2. Collective or public frankpledge (in which sense the word is most commonly used by modern writers) is of very obscure origin, but appears to have existed after the Conquest in the southern and eastern parts of England. The burghers and coorls, or inferior class of freemen, were enrolled in small collective bodies termed *tythings* or *decennaries* (in many instances equivalent to the townships), under the superintendence of a chief pledge or *tything-man*. The *tything* thus organised was bound for the appearance of any one of its mem-

FRAUD

bers under accusation. The 'view of frankpledge' originated in the usage of calling together the individuals who were enrolled in each of these bodies at certain stated times; these meetings were usually held at the court leet, but were not (as Blackstone states it) the main object of that institution, since courts leet were held from an early period in the northern parts of England, in which frankpledge never existed, as well as in the southern. On the view of frankpledge, the members of each *tything* also took the oath of allegiance under the Norman kings. (Turner's *Anglo-Saxons*; Sir F. Palgrave's *Commonwealth of England*.) [COURT, LEET.]

Frapping. On board Ship, is to increase the tension of parallel ropes by binding them together or drawing them towards each other, and therefore tightening them: in desperate cases, even the ship itself may be frapped by cables passed right round the hull to secure unsteady timbers and impart rigidity.

Fratercula. The generic name for the puffins. [MOORMON.]

Fraternities (Lat. *fraternitas*). Associations of laymen in the middle ages, formed for the purposes of general benevolence, and for the discharge of other Christian duties.

Fratricelli (Ital.). In Ecclesiastical History, a sect of Franciscans, founded in Italy towards the close of the thirteenth century, by Maurato and Foscombroni. They made all perfection to consist in poverty, and were condemned by Boniface VIII.; but although it is said that two thousand of their number were burnt by the Inquisition in the fourteenth and fifteenth centuries, the sect existed down to the time of the Reformation, when its members took up the doctrines of Luther.

Fraud (Lat. *fraus*). In Law, the general name for any species of deceit in contracts, either by suppression of truth or assertion of falsehood. The most complete definition of it is that given by Forbes: '*Dolum malum esse omnem calliditatem, fallaciam, machinationem, ad circumveniendum, fallendum, decipiendum alterum adhibitum.*' (Story's *Commentaries on Equity Jurisprudence*.) With a view to the provisions of the English law, frauds may be divided into such as are cognisable by courts of common law, such as are cognisable in equity only, and such as are expressly provided against by statutes. It has been laid down as a general principle, that courts of common law can relieve against the consequences of fraud (by making contracts void, &c.) as well as courts of equity, wherever the fraud is clearly established; and that their inadequacy to provide a proper remedy arises only from their inability to attain the necessary evidence. But however this may be, it has long been a general principle, that courts of equity, in the language of Lord Coke, have jurisdiction over frauds, covins, and deceits, for which there is no remedy by the ordinary course of law. Hence arises one of the three great branches of equity jurisdiction—trust, fraud, account. [CHAM-

FRAUDULENT CONVEYANCES

CELLOR.] The general principles of that jurisdiction appear to be, that the courts will relieve, by considering acts as performed of which the performance has been fraudulently prevented; by setting aside bargains made in ignorance of rights, or where there is material concealment of title, value, &c.; or, finally, misrepresentation in material particulars. Various acts have been made fraudulent, so as to produce the consequence of annulling contracts and avoiding conveyances by statutes: e.g. conveyances with intent to defraud creditors, by 13 Elis. c. 5; voluntary conveyances, 27 Elis. c. 4; various contracts, conveyances, &c. not executed with the formalities required by the Statute of Frauds, 29 Ch. II. c. 3. Some frauds are of a criminal nature, and punishable by indictment; but they are chiefly such as affect the public, or such as are affected by means of false tokens.

By the statute 24 & 25 Vict. c. 96 s. 75 (1861) frauds committed by bankers, merchants, brokers, attorneys, and other agents, in virtue of their employment as such, are made in certain cases misdemeanours, and punishable by penal servitude.

Constructive fraud is said to be any act or contract such as, though not originating in any actual evil design, or contrivance to perpetrate a positive injury upon other persons, yet by its tendency to deceive or mislead other persons, or to isolate public or private confidence, or to impair or injure the public interests, is prohibited by law as within the same mischief as intentional fraud. Such are, in English law, marriage-brokerage bonds, various transactions between parent and child, attorney and client, dealings by trustees with the property of their cestuis que trust, voluntary conveyances, and so forth.

Fraudulent Conveyances. In Law, made void by statutes, are either such as are made with express intent to defraud purchasers and creditors; or voluntary conveyances, from which the law implies such intent.

Fraunhofer's Lines. The dark lines which cross the solar spectrum at right angles to its length; so named after Fraunhofer, who first examined them. [SPECTRUM.]

Fraxinus (Lat.). In Botany, the genus which comprises the Ash-tree. It is a member of the order *Oleacea*, and is known by its dry two-seeded compressed winged fruits. The Common Ash, *F. excelsior*, is one of the most useful of European trees, affording not only an object of picturesque beauty, but a most valuable timber, which from its toughness and elasticity ranks as one of the most important of our native woods. For *Manna Ash*, see *OSYRIS*.

Freckles, (Old Norse, *frekna*; Ger. *flecken* von der sonne: Wedgwood.) Small yellow specks and spots which appear upon the face, especially of fair persons much exposed to the weather. The best application is a dilute spirituous lotion (one part of brandy to eight of water), with a few drops of muriatic acid, so as to render it just perceptibly sour.

FREE TRADE

In Law, a widow's customary dower out of copyholds. It differs from dower mainly in this, that it usually attaches only on lands of which the husband dies seised.

Free Church of Scotland. The name assumed by that large body of Presbyterians in Scotland which seceded from the established church in 1843. [VIRRO.]

Since that time this religious body has continued to flourish in Scotland. In 1851, the period of the last religious census, it had 670 churches complete and 70 building. It has been roughly estimated to comprise 32 per cent. of the inhabitants of Scotland (the established kirk comprising about 34 per cent.). The standards of belief in the Free Church are the Confession of Faith, and the Larger and Shorter Catechisms; besides the Directories and the Form of Church Government, which are to be used rather as regulations than tests. They have, like the kirk, a general assembly. Their ministers are chosen by the members of the church. They have three theological halls, in Edinburgh, Glasgow, and Aberdeen, for the education of ministers; and they have now synods in connection with their church in most of the principal British colonies, although the causes which led to their original disruption from the kirk can scarcely be said to have existed there.

Free Imperial Cities. In the history of the Empire, certain cities which acknowledged no head but the emperor, and were governed by their own magistrates. This privilege constituted them virtually independent republics. Some of these cities formed the Hanseatic league in 1241: that of the Rhenish cities was formed in 1246. [HANSA, HANSE, or HANSEATIC LEAGUE.]

Free Stone. A name applied technically to any kind of stone which may be worked freely, in contradistinction to those that are worked only by the pick or the hammer.

Free Trade. In Political Economy. The principle which underlies all the arguments used by those who advocate free trade, is that no duty should be imposed on any commodity consumed in order to give an advantage to the home producer, or to supply any compensation in consideration of certain colonial or treaty interests. The doctrine that exchange should be free in order to be healthy, is an economical axiom; invasions of this doctrine never having been defended, except on the ground that political expediency or particular burdens justify the violation of a natural law. The support of free-trade principles does not imply that duties on imported commodities must necessarily be abandoned in any sound system of finance, but that such duties should be imposed for revenue purposes only, should not be differential, and if levied on articles manufactured at home, should be coupled with a corresponding excise on home produce.

The arguments alleged by free traders are partly scientific and partly empirical. The object of a protective duty is clearly to raise prices, or in other words to compel a charge for

FREE TRADE

an equal or inferior article in excess of its natural or market price. This is plainly a wrong to the community at large, that is to the mass of purchasers. Nor if a protection were accorded to every producer, would matters be mended. At best the result would be a general rise in prices, in which no one would be benefited, or rather in which everyone would have an inferior article at greater cost. But economical progress depends upon the decreasing cost of production. Hence the plain common sense of free trade and the mischief of protection have been exhibited in a homely formula: that all protection means robbing some one else, the result of universal protection being that everyone could be robbed. Now a system which inflicts manifest injury on the community, needs very powerful reasons for its defence. But it has been found that the reasons alleged are either not sufficient to justify this invasion of natural liberty, or more frequently are baseless and visionary. Again, it is clear that any attempt to regulate prices seriously affects the operation of competition; and consequently, by making values unsettled and fluctuating, causes that to be doubtful which it is the highest interest of the prudent trader to make as certain as possible. The advantage of producer and consumer is equally compromised by unsteady prices.

Secondly, experience has perpetually confirmed the theoretical propriety of free trade. It has been found, first, that increased demand has given greater aggregate profits to unprotected producers, by extending the margin of consumers; and secondly, that capital has flowed more freely, and has been applied more beneficially to employments which government has not pretended to support. The Lancashire manufacturers were convinced so early of this truth, that they petitioned parliament long ago to be freed from the disadvantage of protection. Low prices do not mean low profits; and small profit on single transactions may, if the market be wide, mean great profit in the aggregate.

The natural propriety of free trade was demonstrated in this country by Adam Smith, and exhibited with singular clearness in the merchants' petition drawn up in 1820 by the late Mr. Thomas Tooke. Unfortunately, however, the pressure of a great war, and that ignorance of the simplest economical principles which characterised almost all the statesmen of the early part of the nineteenth century, postponed the consideration of the best way in which national wealth might be increased. The practical demonstration of the wisdom implied in the adoption of free-trade principles was the work of the Anti-Corn-Law League, and particularly of the late Mr. Cobden. When the corn laws were abandoned, the principle of protection was in effect surrendered, for the victory of the League assailed the protective system in its most vital part. [PROTECTION.]

It must not be imagined that free trade has been as yet accepted in this country in all its details. The chief result of the assent given to its axioms is to be found in the acceptance of

FREEHOLD

the principle, in the continual necessity put upon those who are protected to defend their status, and in the application of the rule to finance. It cannot be doubted, however, that much more work remains to be done, before the rule of free trade is applied to all transactions and all interests.

But little progress has been made in other countries in the direction of commercial freedom. The protective system prevails generally on the Continent, though many distinguished economists have exposed and refuted it: of these, none has been more cogent in argument, and more felicitous in illustration, than Bastiat, whose premature death was a very great loss to France. As a rule, professed economists have been urgent in the exposition of free trade doctrines; and those who have studied the conditions and causes of national wealth have rarely failed to range themselves under the banner of free trade.

Freebooters (Ger. *freibeuters*). A name given to some adventurers of all nations, but especially of France and England, who have been conspicuous for courage and intrepidity in executing the most difficult enterprises, and who have made free to appropriate as booty whatever fell under their hands. Their early history is obscure. The South American islands formed the chief theatre of their depredations; and during the latter half of the seventeenth century, they nearly destroyed the commercial operations of the Spaniards in the Indian seas. At the commencement of the eighteenth century, the freebooters sustained a series of disasters, which sensibly diminished their numbers; and since that period the name has been applied indiscriminately to anyone who regards 'the universe as his property,' and appropriates to himself either furtively or forcibly the possessions of another. [FILIBUSTERS.]

Freedmen. In the ancient Greek and Roman Law, the freedmen, or persons manumitted from slavery, formed a distinct class. Although no longer subject to the will of their former master, they were still not free of all relations to him. At Athens the freedman, or one in the state of *ἀνελυθής*, still had to regard his former lord as his *ὑποστάτης* or patron. In Rome, the freedman was called *libertus*, with reference to his master; but the class to which he belonged was termed that of the *libertini*. These

Freedom. [LIBERTY.]

Freehold. In Law, a term which is used in two different senses: 1. To express the quantity of estate which a man may have in lands or tenements; and, 2. To express a tenure by which lands and tenements are held. Thus, an estate of freehold, to satisfy the full acceptance of the term, must be both sufficient in quantity of interest and sufficient in tenure.

1. As to quantity of interest, all estates for term uncertain in duration are estates of freehold; and they are divided into estates of inheritance, and not of inheritance. The first of these are either absolute (fee simple) or limited

FREEMAN

(fee tail, or fee simple conditional). The second are estates for life, or for an uncertain period limited within the term of a life; as, an estate granted to a widow *durante viduitate*. Such estates as this are by the law regarded as estates for life, determinable on a given event. 2. With respect to tenure, freehold tenure is derived from the ancient free socage; and lands held by copy of court roll according to the custom of a manor, viz. copyholds, are not within this denomination. But lands held by custom of the manor, *not* by copy of court roll, are not copyholds, but customary freeholds.

In order, therefore, to give the privileges or impose the duties attached by the law to freeholders (such as serving on juries, voting at county elections, &c.), the estate in respect of which such right or duty attaches must be either for life or a greater interest, and must be held in freehold tenure.

Freeman. In Mediæval Law, one free from servitude, as distinguished from a bondman. The term is now applied to those who have the freedom of a city or borough.

Freemasonry. A well-known institution, the origin of which has given rise to much fabulous narrative and idle speculation. Some derive the mysteries of Freemasonry from those of the priests of Eleusis, and these again from Egypt; others from the secret associations of the Templars. [TEMPLARS; BAPHOMET.] The last opinion was illustrated at great length by M. Barruel (*Mémoires du Jacobinisme*), who fancied both Freemasons and Jacobins to be the relics of a long-established conspiracy for the subversion of religions and empires. A corporation of architects and engineers existed in ancient history under the name of the Dionysiacs of Ionia. They monopolised the building of temples, stadia and theatres, and recognised each other by signs and tokens. A similar fraternity of architects or builders in the middle ages extended over all Catholic countries, and was especially patronised by the see of Rome. It is to this craft that we owe the magnificent Gothic edifices dedicated to religion, which contrast so strongly with the barbarous efforts of those ages in most other departments of art. It is said that this association was introduced into Scotland in the thirteenth century, and about the same time into England, it being ascertained that the abbey of Kilwinning, in the former country, was raised by this fraternity; and it is believed to have continued to exist in these two countries after it had disappeared from the Continent. The Kilwinning and York lodges are respectively the most ancient in either country. The withdrawal of the patronage of the church consequent on the increased supply of architects, the tendency of freemasonry to reject the principles of the church of Rome, and the bloody civil wars of the middle ages, account for the decay of the fraternity in its professional character. But although a severe Act was passed by parliament against the association, in 1426, it appears never to have been

FRENCH POLISH

carried into execution; and King Henry VII. was succeeded as grand-master of the order by Cardinal Wolsey. The office has since been held by several of the kings of England. The first regular grand lodge in London was formed in 1717. The Scottish masons appointed St. Clair of Roslin their hereditary grand-master in 1630; and the office was resigned by his descendant in 1736, when the grand lodge of Scotland was instituted. In 1725, the first French lodge was established; in 1730, the first American; in 1735, the first German. From that period until the present, while the society has existed among ourselves as a mere convivial and benevolent association, and has been patronised even by royalty and the nobility, it has been subjected on the Continent to a variety of suspicions; and it is most probable that political intriguers have availed themselves of the secrecy afforded by it to further their schemes. Indeed, in this country, the 'Royal Arch' degree is said to have been devised by the Scottish Jacobites. Pope Clement XII. excommunicated the Freemasons in Spain and Portugal, where their name was synonymous with that of deists and revolutionists.

The reports of proceedings in grand and private lodges are now published in the *Freemason's Magazine*. (Lawrie's *History of Freemasonry*, Edin. 1804; Anderson's ditto; Preston's *Illustrations of Masonry*; the German *Freimaurer Encyclopædie*, &c.)

Freethinker. A term, usually of reproach, applied to those who reject the ordinary modes of thinking in matters of religion. It is almost synonymous with DEIST [which see].

Freezing Mixtures. When five parts of powdered nitre and five of powdered sal ammoniac are mixed with sixteen parts of water, the thermometer falls in the mixture from 50° to about 10°; so that in this way a degree of cold much below the freezing point of water may be artificially and cheaply obtained, for the salts may be again procured by evaporation and used repeatedly. When ice or snow can be obtained, the most effective freezing mixture is produced by mixing it with about half its weight of salt; it carries the thermometer nearly to 0°. The utmost degree of cold produced by the skilful combination of the best freezing mixtures has not exceeded 140° below 0°.

Freight (Ger. *fracht*). In Mercantile Law, the sum paid by a merchant or other person hiring a ship, or part of a ship, for the use of such ship or part of it for a specified voyage, or for a specified time. Freight must be mentioned, *eo nomine*, in a policy of insurance, and is not covered by a policy on goods.

French Berries. The fruits of several species of *Rhamnus* used for dyeing, as those of *R. infectorius*, *saxatilis*, *amygdalinus*, &c.

French Chalk. A white or greyish kind of Steatite, used for taking grease out of silk, and for slate-pencils.

French Polish. A solution of shell-lac in spirit of wine is the basis of this compound; a

FRENCH WHITE

small quantity of linseed oil is added to it at the time of its application, and it is laid on by a ball of cotton-wool and rapidly rubbed in the direction of the fibres of the wood; when dry, it is finished off by friction with tripoli and oil.

French White. Finely pulverised Talc.

Frenum (Lat. *a rein*). In Anatomy, a name given to some membranous ligaments of the body, as the *frenum linguae*, or ligament of the tongue.

Fresco Painting (Ital. *fresco*, *fresh*). A method of painting by incorporating the colours with the fresh or wet wall plaster, or *sul fresco intonaco*, upon the fresh coat. When dry, such paintings become as permanent as the wall itself. This method is very ancient. It was used by the Greeks, and can be traced even to Egypt, for ordinary purposes of mere wall colouring or staining; but for works of high art, it was not developed until after the time of Giotto; and the first genuine fresco painting, called *buon fresco*, is supposed to be the work of Pietro d'Orrieto, executed in the Campo Santo at Pisa, in 1390. The earlier wall paintings are executed in what the Italians, to distinguish it from *buon fresco*, now call *fresco-secco*, or dry fresco, literally a contradiction. But in the case of *secco* painting, the dry wall was well saturated with water, and the tints, all mixed with lime, were applied while the wall was wet, and when drying were, through the immixture with lime, incorporated with it. *Buon fresco* can only be executed in small portions, just as much as the painter can execute in a single day; the parts therefore marked out for the day's work are distinct portions of figures or objects, which are not injured by being surrounded by a sharp outline. (See the article 'Fresco' in the Supplement to the *Penny Cyclopædia*; the *Appendices to the Reports of the Commissioners on the Fine Arts* for 1842 and 1843; and Mrs. Merrifield's *Art of Fresco Painting*, &c. London 1846.)

Freshwater Deposits. All materials thrown down after suspension in water, or conveyed by moving water and left behind when the current has diminished in force, or left behind after the evaporation of water, are strictly *aqueous deposits*. [Aquous Rocks.] Of these it is clear that some will be due to rivers, lakes, and fresh water filtered into caverns or rising in springs, and the rest to the sea. The former come under the general designation of *freshwater deposits*, and contain usually some marks of adjacent land, or of lakes, or pools. Thus fragments of leaves, insect cases, shells of snails, and shells of lymneæ or planorbis, and even bones of quadrupeds, are amongst them. They are not so large or abundant as marine deposits, but are often interesting as indicating the position of ancient land.

Fret (Fr. *frette*). In Architecture, an ornament consisting of one or more small fillets, meeting in vertical and horizontal directions. The section of the channels between the fillets is irregular. The

FRICITION

preceding diagram shows two sorts of simple frets; but they are often much more complicated in their design.

Frets. The cross bars on the finger-boards of stringed instruments of ivory or brass, by pressure whereon with the finger the string is stopped to produce a certain note in the scale. The use of frets is still continued on the Spanish guitar, and they were formerly in constant use for learners upon what was called the bass-viol; they were taken off when the pupil had learnt by practice to measure the accurate distance of the stops. On lutes and viols they were always permitted to remain.

Fresa. [ODIN.]

Friability (Lat. *friabilis*, *that may be broken*). The property by which substances admit of being crumbled into powder by gentle friction.

Friar (Fr. *frère*, Lat. *frater*, *brother*). A brother or member of any religious order; but more exclusively applied to those of the Mendicant Orders, of which the four chief were the Dominicans (Black Friars), Franciscans (Grey), Carmelites (White), and Augustines. [ORDERS, MENDICANT.]

Friar's Balsam. The compound tincture of benzoin of the London Pharmacopœia. It is an alcoholic solution of benzoin, styrax, tolu balsam, and aloe; it is used as a stimulating application to wounds and ulcers.

Friction (Lat. *frictio*, from *frico*, *I rub*). In Mechanics, the resistance produced by the rubbing of the surfaces of two solid bodies against each other. If the surfaces of bodies were perfectly smooth and polished, they would slide along one another without suffering any resistance from their contact, and all the simple relations between power and resistance determined by theory in respect of the different machines would hold good without any modification whatever. But this state of perfect polish never exists. The surfaces of all bodies with which we are acquainted, even when most carefully polished, retain a greater or less degree of asperity, which prevents them from sliding over one another without impediment; and in many cases the resistance thus created amounts to a large proportion of the whole resistance to be overcome. In order, therefore, to ascertain the real value of the effect of powers applied to machinery, it is necessary to determine the amount of the friction, and to add this new resistance to that which is given by the theory of mechanics.

The determination of the laws of friction, and of its amount with respect to particular substances, has occupied the attention of many experimental philosophers and mathematicians, Amontons, Euler, Desaguliers, Vince, &c.; but the first complete set of experiments on the subject was made by Coulomb about the year 1780. His results, though they have been partly modified by subsequent experiments, throw much light upon the subject, and are of great value to the practical engineer.

Assuming the pressure as equal to 100 parts,

FRICTION

the friction of oak against fir was 66 in the direction of the fibres, but amounted only to 16 when moved with the velocity of a foot each second; the friction of oak against oak in the direction of the fibres was 43, and across them only 27, the effect being further reduced by motion to 10; the friction of fir against fir in the direction of the fibres was 56, which sank to 17 during motion; the friction of elm against elm in the direction of the fibres was 46, and reduced by motion to 10. On the other hand, the friction of copper upon oak, lengthwise, was 8 at the commencement of the motion, but increased to 18 when the velocity was a foot in a second; the friction of iron upon oak with the initial velocity was 11, and was increased by the motion to 18. But the mutual friction of metals appeared in general to be scarcely, if at all, affected by motion. In these experiments no unguents were used.

Coulomb also investigated the effect of velocity upon the friction of rubbingsurfaces, and also the influence of pressure and extent of surface upon friction. The following is a brief summary of the general results of Coulomb's experiments respecting the friction of bodies *sliding* on each other.

1. Between similar substances, under similar circumstances, friction is a constant retarding force.
2. Friction is greatest between bodies whose surfaces are rough, and is lessened by polishing them.
3. It is greater between surfaces composed of the same material, than between the surfaces of heterogeneous bodies.
4. If the rubbing surfaces remain the same, the friction increases directly as the pressure.
5. If the pressure continue the same, the friction has no relation to the magnitude of the surface.
6. The application of grease in general diminishes the friction, though in very different degrees.

The obstruction which a cylinder meets with in rolling along a smooth plane is quite distinct in its character, and far inferior in its amount, to that which is produced by the friction of the same cylinder drawn lengthwise along a plane. For example, in the case of wood *rolling* on wood, the resistance is to the pressure, if the cylinder be small, as 16 or 18 to 1,000; and if the cylinder be large, this may be reduced to 6 to 1,000. The friction from sliding, in the same cases, would be to the pressure as 2 to 10, or 3 to 10, according to the nature of the wood. Hence, by causing one body to roll on another, the resistance is diminished from 12 to 20 times. It is therefore a principle in the composition of machines that attrition should be avoided as much as possible, and rolling motions substituted whenever circumstances admit.

On this principle depends the advantage resulting from the application of *friction wheels* and *friction rollers*. The extremity of an axle C, instead of resting in a cylindrical socket, is made to rest on the

circumferences of two wheels, A and B, to the

axles of which, *a* and *b*, the friction is transferred, and consequently diminished in the ratio of the radius of the wheel A to the radius of the axle *a*. This ingenious contrivance appears to have first been applied by Henry Sully, in the year 1716. (*Descr. Abrégée d'une Horloge*, &c. Bordeaux 1716.)

The following are deductions from Coulomb's experiments relative to the friction of rolling bodies: 1. Like the friction of sliding bodies, it is a constant force. 2. It is affected by the nature of the surface so far as polish is concerned; but is not lessened by the interposition of unctuous substances. 3. It is less between heterogeneous than between homogeneous substances. 4. It is directly proportional to the pressure. 5. It has no relation to the magnitude of the surface. 6. It is much less than in the case of sliding surfaces, and varies in the inverse ratio of the diameter of the rolling body.

The friction of the axle of a wheel or pulley (whether the axle itself turns, or the wheel turns on the axle) is of a different kind from that of a cylinder rolling on a plane. It is less than that of sliding, but greater than that of rolling bodies, and follows in all respects the laws of the friction of sliding bodies. A great advantage is here obtained by greasing the surfaces. By the application of fresh tallow the friction is reduced to one-half.

Coulomb's experiments were also directed to ascertain the resistance arising from the rigidity of ropes when bent round rollers or cylinders. The results are as follows: 1. The resistances of ropes are directly proportional to the tensions to which they are subjected. 2. The resistance increases with some determinate power of the diameter, and is greatest in ropes that have been strongly twisted, or are coated with tar. 3. The resistances are inversely as the diameters of the cylinders about which the ropes are bent.

When a rope is wound more than once round a cylinder, the resistance increases in a geometrical progression. This principle is frequently applied in practice: thus, in arresting the progress of a vessel, a rope is wound round a post, and a very few turns is sufficient to overcome any force which the rope is capable of withstanding.

A valuable series of experiments on friction was made by Mr. George Rennie, the details of which are given in the *Phil. Trans.* for 1829. The following are a few of the results: Assuming as before the pressure equal to 100 parts, the friction of steel upon ice is 1·4; ice upon ice 2·8; hard wood upon hard wood 13; brass upon wrought iron 13·5; soft steel upon soft steel 14·6; leather upon iron 26; granite upon granite 30; yellow deal upon yellow deal 36; sandstone upon sandstone 36; woollen cloth upon woollen cloth 43. Some of the conclusions deduced by Mr. Rennie are as follows: 1. In fibrous substances, such as cloth, friction is increased by surface and time, and diminished by pressure and velocity. 2.

FRICTION-WHEELS

In harder substances, such as woods, metals, and stones, the friction is directly as the pressure, with regard to surface, time, or velocity. 3. Friction is greatest with soft, and least with hard, substances. 4. The effect of unguents is as the nature of the unguents, with reference to the substances to which they are applied.

In the *Mémoires de l'Institut* for 1833, two very extensive sets of experiments are described, which were made by M. Morin, at Metz, under the auspices of the French government, for the purpose of verifying or correcting the results of Coulomb. In general, M. Morin's results differ widely in absolute amount from those of Coulomb, giving in some instances ratios three times as great; but they point to, and indeed fully establish, the same general conclusions. (Coulomb, *Théorie des Machines Simples*, Paris 1821, and *Mémoires des Savans Étrangers*, tom. ix. and x.; Ximenes, *Teoria e Pratica delle Resist. de Solidi ne' loro Attriti*, Pisa 1782; Vince, *Phil. Trans.* 1786; Ronnic, *Phil. Trans.* 1829; Morin, *Mémoires de l'Institut*, 1833; *Encyclopædia Britannica*, art. 'Mechanics,' &c.)

Friction-wheels. [FRICTION.]

Friday (Ger. Freitag). The sixth day of the week. The name is derived from FREYA [which see].

Friendly Societies or Benefit Societies. Voluntary associations of subscribers, for the purpose of forming a fund for the assistance of members in sickness, or other occasions of distress. It is supposed by Mr. Turner (in his *History of the Anglo-Saxons*) that the ancient guilds originated in associations of this kind. It is certain that in countries where the privileges of guilds are still permitted, the trading society is called on to contribute to the occasional wants of the members of each association. Of the various means that have been suggested in this view, and for enabling the poor to provide a resource against sickness and old age, none seem so likely to accomplish their object as the institution of friendly societies and savings-banks. The former are founded on a principle of mutual insurance. Each member contributes a certain sum, by weekly, monthly, or annual subscriptions, while he is in health; and receives from the society a certain pension or allowance when he is incapacitated for work by accident, sickness, or old age. Nothing, it is obvious, can be more sound than the principle of these associations. If a number of individuals under thirty or thirty-five years of age form themselves into a society, and subscribe each a small sum from their surplus earnings, they are able, owing to the general exemption from sickness until a comparatively late period of life, to secure a comfortable provision for themselves in the event of their becoming unfit for labour. Anyone who should trust to his own isolated efforts would plainly be placed in a far more hazardous position. Whenever an unfavourable contingency exists, the best and cheapest way of ob-

FRIGID ZONE

viating its effects is by uniting with others, each subjecting himself to a small privation, so that none may be overwhelmed by any great calamity. Hence the paramount utility of the societies in question.

Benefit societies commenced their legal existence in January, 1793, and since that time have been a frequent object of legislation, the provisions of the Act 18 & 19 Vict. c. 63 being the principal rule for their present administration. For minute information on the subject, the reader is referred to Mr. Scratchley's work on *Associations for Provident Investment*.

Advantageous as has been the institution of these societies, it cannot be denied that they have too often been delusive. Great errors, for instance, have arisen from their fixing too high a scale of allowances. At their first institution they are necessarily composed of members in the prime of life; there is, therefore, comparatively little sickness and mortality amongst them. In consequence their funds rapidly accumulate; and the projectors are tempted to give too large an allowance to those members who are occasionally incapacitated. But the circumstances under which the society is placed at an advanced period are materially different. Sickness and mortality are then comparatively prevalent. The contributions to the fund decline at the time that the outgoings increase; and it has not unfrequently happened that the society has become altogether bankrupt; and that the oldest members had been left, at the close of a long life, destitute of all support from a fund on which they had relied, and to which they had largely contributed.

The latest Acts place friendly societies under the direct control of a government registrar, who grants a certificate for their establishment on seeing that the provisions of law are complied with in their regulations. The Act also divides these societies into *registered societies*, which are allowed to embrace only a portion, and *certified societies*, which embrace all the objects, contemplated by the statute. The latter only can invest their funds with the Commissioners for Reduction of the National Debt.

Friends, Society of. [QUAKERS.]

Friesland Green or Brunswick Green.

An oxichloride or an ammonio-chloride of copper.

Frieze (Fr. frise, Ital. fregio). In Architecture, the member of the entablature of an order between the architrave and the cornice. It is always plain in the Tuscan; ornamented with triglyphs and sculpture in the Doric; in the Ionic, it is occasionally in modern or Italian architecture swelled, in which case it is called a *pulvinated* or *cushioned frieze*; and in the Corinthian and Composite, it is variously decorated according to the taste of the architect.

Friga. In Northern Mythology. [ODIN.]

Frigate (Fr. frégate, Span. fragata). The name applied to a ship with one covered gun deck, and having her upper deck flush.

Frigid Zone. The space about either pole

FRIGIDARIUM

of the earth terminated by the parallel of $76\frac{1}{2}$ degrees of latitude. At this parallel the sun at noon, in the middle of winter, is 90 degrees from the zenith; and consequently, were it not for the refraction, would not be completely visible even at noon above the horizon. Within this parallel the sun continues invisible in winter, and constantly visible in summer, for a shorter or longer space of time, depending on the distance of the place from the pole, where the sun remains for one half the year above the horizon, and the other half below it. [ZONE.]

Frigidarium (Lat.). In ancient Architecture, the apartment in which the cold bath was placed. It is sometimes used to denote the bath itself.

Frilazin. Among the Anglo-Saxons, a class of persons answering to the Roman liberti. [FREEDMEN.]

Fringes. A term used in Optics to denote the coloured bands resulting from diffraction.

Fringilla (Lat. *a chaffinch*). A Linnæan genus of Passerine birds, characterised by a broad-based, sharp-pointed, strong, conical bill: now raised to the rank of a family, *Fringillidæ*; including the buntings (*Emberiza*), the cross-bills (*Loxia*), the grosbeaks (*Coccothraustes*), the linnets (*Linaria*), canary-birds (*Canaria*), finches (*Carduelis*), and many exotic subgenera of seed and grain eating Conirostral birds.

Frith or Firth (Lat. *fretum, a narrow sea*). A term chiefly applied to a narrow and deep inlet of the sea upon a river, as the Frith of Forth in Scotland. This term corresponds to the *fjord* of the Danes and Norwegians, and belongs to the same root with *Ger. fahren*, to pass over (*Gr. πηδῶν, pédos*, as in *Βόταρος*); whence *ferry, ford, furt* (Ger.), as in Frankfurt, Erfurt, &c.

Frithsoken (A.-Sax.). In Law, a liberty of having frankpledge, or surety of defence.

Fritillaria. In Botany, a genus of Liliaceous plants, including the *F. imperialis* or *Crown Imperial*.

Fritt. The materials of glass are first mixed together, and heated, so as to expel water, and induce fusion: the mass thus obtained is called *fritt*.

Frog. [BATRACHIA and RANA.]

Frog or Frush. In Farriery, the hard projecting substance in the hollow of a horse's foot.

Fronde (Lat. *frons, frondis*). A combination of stem and leaf in one organ, as in *Lemna*, *Marchantia*, and such plants. The term is also applied to the leaves of ferns.

Fronde, War of the. The war maintained by the malcontent partisans of the parliament in France, under the regency of Louis XIV., against the government of Cardinal Mazarin. The name of *Fronde* (*sling*) was given to this war in consequence of some incidents in a street quarrel, of which various accounts have been given. The party opposed to government was called that of the *Fronde*; and the word *frondeurs* has hence acquired in the French language the signification of discontented politicians.

FUCHSIA

The French Record Department has lately published an extensive and curious collection of *Mazarinades*, political squibs of the period of the Fronde

Frondose (Lat. *frondosus, leafy*). In Botany, a term applied to plants with leaves developed in an unusual manner either in regard to their number or size.

Frons (Lat.). In Mammalogy, the region of the cranium between the orbits and the vertex.

Frons. In Ornithology, the space between the base of the bill and the vertex.

Frontal Bone. The front bone of the head, which forms the forehead.

Frontal Sinus. A cavity in the frontal bone, placed over the orbit, on each side.

Frontier (Fr. *frontière*, Ital. *frontiera*). The boundary of a state, or the territories adjacent to the boundary. The best frontier is the sea; the next best, great rivers or mountains, as the Rhine, Rhône, Alps, and Pyrenees. Prussia has the worst frontier of any European state.

Frontispiece. In Architecture, the face or fore front, of a house, but more usually applied to the decorated entrance to a building. This term is also applied to the ornamental first page of a book, being, as the derivation implies, that part which first meets the eye.

Frontlet. In Ornithology, the margin at the head behind the bill of birds, generally clothed with rigid bristles.

Frost. [CLIMATE; ICE.]

Fruit (Fr.; Lat. *fructus*). In Botany, the ovary or the pistil arrived at maturity; but the term is commonly extended to whatever is combined with the ovary when it is ripe. It comprehends many kinds of what are commonly called *seeds*; as those of corn, buckwheat, caraway, parsley, &c.; as well as the succulent inflorescence of the pineapple, which is a mass of ovaries and their envelopes in a consolidated condition.

Frustules (Lat. *frustum, a fragment*). In Botany, a term applied to the joints into which the *Diatomaceæ* separate. They contain a large proportion of siliceous matter, and hence, being capable of retaining their form after the vegetable constituents have died, they are often found preserved in a fossil state.

Frustum (Lat.). In Geometry, a part cut off from a solid. The term is rarely used except in the cases of pyramids and cones, and then it is usually understood to refer to that part of the solid which is included between any two planes of section.

Frutex (Lat. *a shrub*). In Botany, a plant whose branches are perennial, and proceed directly from the surface of the earth without any supporting trunk.

Fuchsia (after Leonard Fuchs, a German botanist). A plant belonging to the order *Onagraceæ*. The genus is distinguished by its long funnel-shaped four-part coloured calyx, its four petals, its eight exserted stamens, and its long style. There are many distinct species.

FUCUS

but the most commonly cultivated *Fuchias* are varieties produced by the skill of the hybridiser.

Fucus (Lat.; Gr. *φύκος*, seaweed). A genus of seaweeds comprising those with olive-coloured flat or compressed forked fronds, such as *F. serratus* and *nodosus*. They furnish a large proportion of the seaweed thrown upon the shore, and collected as manure. Formerly they were used for making kelp.

Fuel (Nor. Fr. *fuayl*). Any combustible substance which is used for the production of heat constitutes a species of fuel; and in this extended sense of the term, alcohol, wax, tallow, coal-gas, oil, and other inflammable bodies which are occasionally used, especially in the chemical laboratory, as sources of heat as well as light, might be included under it. But the term *fuel* is more properly limited to coal, coke, charcoal, wood, and a few other substances, which are our common *sources of heat*, and as such are burnt in grates, stoves, fireplaces, and furnaces.

In this country coal, from its abundance and cheapness, is the commonly employed fuel; but where wood is abundant, or where its value is little more than that of felling it, it is used either in its original state or in the form of charcoal. But whatever substance is used, the essential ultimate elements of fuel are carbon and hydrogen; and the heat which is evolved by their combustion is derived from their combination at high temperatures with the oxygen of the air; the principal results or products of this combustion are carbonic acid and water, these escaping into the atmosphere by the flue or chimney generally attached to furnaces and fireplaces.

It is essential to good and profitable fuel that it should be free from moisture; for unless it be dry, much of the heat which it generates is consumed in converting its moisture into vapour: hence the superior value of old, dense, and dry wood, to that which is porous and damp; hence also the greater quantity of heat evolved during the combustion of charcoal as compared with that of wood, for even the driest wood always retains a certain quantity of water; hence also coke gives out more heat than pit coal, partly because it is absolutely dry, and partly because during the combustion or heating of coal, tar, oil, water, and inflammable gases are evolved, all of which carry off a certain proportion of the heat in a latent form. A pound of dry wood will, for instance, heat 35 pounds of water from 32° to 212°, and a pound of the same wood in its fresh state will not heat more than 25 pounds to the same temperature; the value, therefore, of different woods for fuel is nearly inversely as their moisture, and this may be roughly ascertained by finding how much a given weight of their shavings loses by thoroughly drying them.

Charcoal is itself very hygrometric, and when exposed to air increases in weight to the amount of 10 or 12 per cent., chiefly in consequence of the absorption of humidity: a pound of dry

FUEROS

charcoal is capable of raising, when properly burnt, 73 pounds of water from the freezing to the boiling point.

The different kinds of pit coal give out variable quantities of heat during their combustion; upon an average, one pound of coal should raise 60 pounds of water from the freezing to its boiling point. The heating power of coke as compared with coal is nearly in the ratio of 75 to 69: a pound of good coke will heat from 64 to 66 pounds of water from 32° to 212°; its power, therefore, is about nine-tenths that of wood charcoal.

The value of dried turf and peat as fuel is liable to much variation, and depends partly upon their density, and partly upon their freedom from earthy impurities. A pound of turf will heat about 26 pounds of water from 32° to 212°, and a pound of dense peat about 80 pounds: by compressing and drying peat its value as a fuel is greatly increased.

The following table, by Dr. Ure, shows the quantity of water raised from 32° to 212° by one pound weight of the different combustibles enumerated in the first column; it also shows the number of pounds of boiling water which the same weight of fuel will evaporate, and the quantity of atmospheric air absolutely consumed during combustion. The quantity of air, however, as given in the last column, is much less than would be necessary in practice, where much of the air passes the fuel without coming into contact with it so as to have its oxygen consumed. The heating power also, as represented by this table, can seldom be *practically* attained.

Combustible	Pounds of Water which a Pound can raise from 32° to 212°	Pounds of Boiling Water evaporated by One Pound	Weight of Atmospheric Air at 32° required to burn One Pound
Dry wood . .	85·00	6·36	5·96
Common wood .	26·00	4·72	4·47

Alcohol . .	82·00	9·56	11·60

Fueros. The term by which in Spain the peculiar rights and privileges of certain provinces are distinguished. It corresponds to the old French word *for* or *fors*; and is said to be derived either from the Latin word *forum*, or (more probably) from the Spanish *fuera*, which signifies *outside* or *without*, thereby indicating the difference between the administration of the provinces in which the fueros prevail from that of other parts of the Spanish monarchy. There can be little doubt that the origin of these fueros may be fairly associated with the political existence of the brave Cantabrians, who were never wholly subjugated to the Roman yoke, and who even when partially vanquished still maintained their ancient laws and customs inviolate. From their earliest origin the Basque Provinces enjoyed certain privileges unknown to the rest of the Spanish kingdom, and which,

FUEROS

though originally not reduced to writing, and existing like our own common laws in the traditions of the country, were mutually and religiously observed both by the monarch and the people. In this state they remained till the year 1235, when, on the accession of Thibault, a French prince, to the crown of Navarre, some misunderstanding arose respecting the nature and extent of the *fueros*, and it became necessary to embody them in a written code, which, with some considerable enlargement sanctioned by Charles V., was, down to the period of the last revolution, faithfully recognised by all the monarchs of Spain as the magna charta of the Basque Provinces, until the revolution of 1833; nor can it well be doubted that the Carlist war became a lengthened struggle chiefly from the skilful way in which a question of succession was mixed up with the subject of the Basque *fueros*.

Though the immunities of the provinces, Guipuzcoa, Alava, Biscay, and Navarre, exhibit considerable difference in detail, their main features are marked by a striking uniformity, the form of government in each province being essentially republican in all its branches. In the province of Biscay, for instance, which, with a few modifications, may serve as an example for the other provinces, the royal authority is purely nominal. The only privilege of the crown consists in nominating the *corregidor*, the highest officer in the state; but even this appointment is subject to the approval of certain members (called *deputations*) of the *junta* or states, in whose assemblies he has a seat and vote. In the *junta* is vested the chief management of affairs. This assembly forms, with the exception of the American congress, by far the most popularly constituted representative body in modern times, the right of voting being conferred on every man who possesses a domicile within the lordship; and its chief duties consist in administering the affairs of the commonwealth, in collecting the taxes, in providing for the protection and defence of the country, in nominating the official servants of the government, and in forming of itself a court of appeal from the decisions of the *corregidor*. Of the privileges and immunities of the province itself, the following are the principal: Freedom from paying any imposts but those due from the inhabitants to their own lordship, and which are fixed by themselves, and additionally whatever gratuitous contributions may be deemed necessary to meet the extraordinary emergencies of the state; the enjoyment of the privileges of nobility in the Castilian dominions on merely proving a descent from pure Biscayan blood; exemption from appearing before any tribunal beyond the limits of the lordship; to tolerate no royal intendant or comptroller within the province; to permit no *estanco* or royal monopoly, as in the rest of Spain; exemption from duty on imported merchandises; to have no royal administration, except that of the post-office; to admit no Spanish troops within the territory; to furnish

FULLER'S EARTH

no recruits for the royal army; to defend their territory with their own means and blood; and to visit with summary punishment all who may be convicted of extortion, or of any attempt to injure or even to interfere with the constitution of the province. (Hallam's *Middle Ages*, ch. iv.; Lord Carnarvon's *Portugal and Galicia*; F. Michel, *Le Pays Basque*.)

Fuga or **Fugue** (Lat. *fuga*, *flight*). In Music, a composition wherein the different parts follow each other, each repeating the subject at a certain interval after the preceding part.

Fugleman or **Flugelman** (Ger. *flügel*, a wing). A non-commissioned officer, appointed to take his place in front of a regiment as a guide to the soldiers in the movements of the drill: the custom has now fallen into disuse.

Fulcra (Lat. *prope*). In Botany, a term denoting the tendrils, prickles, spines, hooks, or other processes by which plants are enabled to support themselves upon other plants.

Fulcrum (Lat.). In Mechanics, the fixed point about which a lever moves. [LEVER.]

Fulgura (Lat. *fulgur*, an *effulgence*). The generic name of certain singular insects of the order *Homoptera*, and family *Cicadaria*, which have the forepart of the head produced in the form of a snout, or large hollow receptacle; and the antennæ inserted beneath the eyes, only three-jointed, and terminated by a slender bristle. It is asserted by one naturalist (Mad. Merian), that the frontal projection emits a bright light; but others who have had opportunities of making observations on the living lantern-fly, as the larger species is called, have not witnessed the exercise of its illuminating powers, if it really possess them.

The *Fulgura lanternaria* is a native of South America; the *Fulgura candellaria* of China. There are many other species included in the Linnæan generic character, but which now form the subgenera *Otiocerus*, *Lysitra*, *Cixius*, *Paciloptera*, *Issus*, *Anotia*, *Delphax*, *Fulgura proper*, &c., in the family *Fulgoroidea*.

Fulguration (Lat. *fulguratio*, from *fulgur*, lightning). A term applied by the assayer to the sudden brightening of the fused globule of gold or silver, when the last film of oxide of lead or copper leaves its surface.

Fulgurites (Lat. *fulgur*, lightning). Fused or vitrified tubes formed by the passage of lightning through sand, whence has originated the designation of *fossil lightning*, which is sometimes applied to them.

Fulica (Lat.). The name of a genus of Wading birds of the family *Macroductyli*, now restricted to those which have a strong, moderate-sized, straight, conical, and compressed bill, with a dilated naked plate at the base of the upper mandible: the toes are furnished at the sides with a scalloped membrane; the wings middle-sized. The British species, or common coot (*Fulica atra*), is well known: all its congeners approach more or less to its sooty or blue-black colour.

Fuller's Earth. An earthy, hydrated silicate of alumina, composed, when pure, of

FULLING

45 per cent. of silica, 20 alumina, and 25 water. Like other soft aluminous minerals, it has the property of absorbing grease, and on that account was formerly used in large quantities by cloth manufacturers in fulling cloth, whence the name of *fuller's earth*. Its exportation was formerly forbidden under severe penalties, but the consumption has now fallen off considerably, in consequence of the substitution of soap and other substances.

Fulling (Lat. *fullo*, a cloth-dresser). The art of cleansing, scouring, and pressing stuffs, cloths, stockings, &c., to render them stronger, firmer, and closer; it is also called *milling*, because these cloths, &c. are in fact scour'd by a water-mill. (Ure's *Dictionary of Arts, &c.*)

Fulminates (Lat. *fulmen*, a thunderbolt). Compounds of the fulminic acid with various bases, all more or less possessed of the property of exploding by heat or friction.

The fulminating silver and mercury are objects of manufacturing interest; the former being used in detonating *bonbons*, and the latter more largely as a priming for the percussion caps of gunlocks.

Fulminating Mercury, Fulminate of Mercury [$2(\text{HgO})$, Cy_2O_3].—This compound is prepared by dissolving 100 grains of mercury in a measured ounce and a half of nitric acid, aided by heat. This solution is to be poured, when cool, into two measured ounces of alcohol in a porcelain basin, and gently warmed: it soon effervesces and evolves ethereal vapour, and if the action is too violent, it must be quelled by cooling the vessel, or by the addition of a little cold alcohol. During this action a grey precipitate falls, which is to be immediately separated by decantation and filtration, washed with small quantities of distilled water, and carefully dried at a heat not exceeding 100° . The above quantity of mercury should yield about 120 grains of the powder. If the product is mixed with metallic mercury, it may be purified by solution in boiling water, from which it is deposited in silky acicular crystals. This dangerous compound is now in considerable demand for the manufacture of percussion caps. It is introduced, mixed with other ingredients, into the caps, closely compressed, covered with a resinous varnish, and subsequently carefully dried. When fulminating mercury is heated to about 300° , it explodes suddenly with a bright flame: it also detonates by friction or percussion (especially when placed in contact with particles of sand or glass); by the electric spark; and by contact of concentrated sulphuric and nitric acids. The gases evolved by its explosion are carbonic acid, nitrogen, and the vapour of mercury.

Fulminating Powder. A compound of three parts of nitre, two of carbonate of potash, and one of sulphur, carefully mixed and dried: about twenty grains of this powder heated upon an iron plate over a slow fire become brown and pasty; a blue flame then appears upon it, and immediately after, the whole explodes with a stunning report.

FUMIGATION

Fulminating Silver, Fulminate of Silver [$2(\text{AgO})$, Cy_2O_3].—This dangerous compound is prepared as follows: 100 grains of fused and finely-powdered nitrate of silver are added to an ounce of warm alcohol in a large basin; an ounce of nitric acid is then added, and presently effervescence ensues and a powder falls: as soon as this appears white, cold water is added, and the powder collected upon a filter, washed, and carefully dried at a temperature of 100° . In collecting and handling this powder the utmost caution is requisite; it should be made in small quantities only, and not touched with anything hard, for it has exploded upon the contact of a glass rod under water. The feather of a common quill serves to collect it; and it should be kept either under water, or, if dry, in a wide-mouthed vessel covered by paper, and not in a stoppered or corked phial. Fulminating silver is a grey crystalline powder; it acquires a dingy hue by exposure to light; it dissolves in from 30 to 40 parts of boiling water, and as the solution cools, nearly the whole is again deposited in minute crystals. It detonates with great violence when heated, or touched by any hard substance, or when placed upon a piece of rock-crystal and touched in the slightest manner by another crystal; it also detonates upon the contact of sulphuric acid, and by the electric spark.

Fulminic Acid. An acid composed of 2 equivalents of cyanogen = 52, and 2 of oxygen = 16, corresponding therefore in ultimate composition with the *cyanic acid*. In combination with the oxide of silver and oxide of mercury, this acid constitutes fulminating silver and fulminating mercury.

Fumaramide. A white powder formed when fumaric ether is mixed with ammonia.

Fumariaceæ (Fumaria, one of the genera). A natural order of herbaceous hypogynous Exogens, inhabiting all temperate climates, and related to *Papaveraceæ* so nearly as to be incorporated with them by some writers. Their sensible properties are not of any value. A few are objects of cultivation for their beauty.

Fumaric Acid. An acid existing in the *Fumaria officinalis*, or common fumitory: it may also be produced by the action of heat on malic acid.

Fumarimide. A red powder formed on heating bimalate of ammonia.

Fumigation (Lat. *fumigo*, from *fumus*, smoke). The diffusion of certain vapours through the air, for the purpose of destroying contagion and infection: goods are also fumigated for the same purpose. Acid vapours have frequently been used for this purpose; there are, however, few which are effectual, and some of them, such as vinegar, only serve to cover bad smells without destroying noxious effluvia. There is no disinfectant so certain in its effects as *chlorine*; it is cheap, and easily obtained either from muriatic acid and black oxide of manganese, or from a mixture of salt, sulphuric acid, and black oxide. In inhabited rooms it requires to be cautiously used, in consequence

FUMING LIQUORS

of its bad effects upon the respiratory organs; but even here it may be so extensively diffused as to be effective in destroying noxious matters, without serious injury to persons who breathe the atmosphere. When a room can be shut up it may be freely used, and it should be generated in saucers placed in different parts of the apartment (if a large one); and not upon the ground, but upon shelves high up in the room, for chlorine being heavier than air is thus more effectually diffused. Infected clothes and furniture may at the same time be subjected to this action. Of all common diseases, the scarlet fever is that which appears to require the most scrupulous attention to careful fumigation.

Fuming Liquors. Certain compounds which exhale visible fumes, or in common language *smoke*, when exposed to air, were so called by the old chemists. *Boyle's fuming liquor* is sulphuret of ammonium; *Cadet's fuming liquor* is an arsenical compound, now termed *oxide of kakodyle*; the *fuming liquor of Libavius* is the anhydrous bichloride of tin.

Function (Lat. *functio*, from *fungor*, I discharge). One quantity is said to be a *function* of another, or of several others, when its value depends upon those of the latter. Thus the area of a triangle is a function of its three sides, and $y = a + bx + cx^2$ is a function of a , b , c and x . Functions receive distinctive names according to the *nature* of the dependence above referred to. Thus the function above written is said to be an *algebraical* function of x , since y is obtainable from x by the performance of a limited and definite number of algebraical operations. $\log x$, $\sin x$, a^x , on the other hand, are said to be *transcendental* functions of x , and, for obvious reasons receive the distinctive names of *logarithmic*, *trigonometrical*, and *exponential* functions. The general fact that y is a function of x is usually expressed by the notation $y = F(x)$, in which the *functional symbol* F merely indicates that y depends upon x in some definite manner; in other words, that the expression of y in terms of x has a definite *form*. The symbol $F(y)$, used in the same investigation, would indicate a quantity which depends upon, or is derivable from y , as y depends upon, or is obtainable from x . Another expression for $F(y)$, therefore, would be $F[F(x)]$ or, more concisely, $F^2(x)$. Similarly $F^m(x)$ would denote the result of m successive operations of the *same kind*, the *subject* operated upon each time being the *result* of the immediately preceding operation. Thus if

$$\begin{aligned} F(x) &= 1 + 2x, \\ F^2(x) &= 1 + 2(1 + 2x) = 3 + 4x, \\ F^3(x) &= 1 + 2(3 + 4x) = 7 + 8x, \end{aligned}$$

and so on. According to the above definition, we have obviously $F^{m+n}(x) = F^m[F^n(x)]$, when m and n are positive integers; and an important extension at once suggests itself. If we agree that the last relation shall hold for *all* values of m and n , then $F^n(x)$ would denote the *subject* or *argument* x itself, and $F^{-1}(x)$ the *inverse* function of $F(x)$, or that quantity from

FUND, SINKING

which the result x would be obtained by the operation F . Thus, in the above example, $F^{-1}(x) = -\frac{1}{2} + \frac{1}{2}x$.

That branch of mathematics wherein the *forms*, rather than the *values*, of functions are investigated, is called the *calculus of functions*. The following may be taken as a simple example of the kind of questions therein examined: What function of x is that which, when multiplied by the same function of y , gives the same function of $x + y$? Representing the unknown function by F , this is equivalent to the solution of the *functional equation* $F(x)F(y) = F(x + y)$. For an exposition of the general methods of treating such equations, see 'Calculus of Functions,' in the *Encyclopædia Metropolitana*, by Prof. de Morgan; also Babbage's *Elementary Treatise on the Calculus of Functions*; Lagrange, *Théorie des Fonctions Analytiques*; Cauchy, *Cours d'Analyse* and *Éléments du Calcul Infin.*; Peacock's *Algebra*, &c.

Functions, Laplace's. [LAPLACE'S COEFFICIENTS AND FUNCTIONS.]

Functional Determinant. [JACOBIAN.]

Fund, Sinking. It has commonly been the practice, when a portion of public debt has been created, to sustain the credit of this financial expedient, by making some provision for the gradual liquidation of the capital sum borrowed. The most obvious method is the creation of terminable annuities, the payment of interest on which is in this manner accompanied by a restitution of part of the principal. But terminable annuities have never been popular in this country, and have always been negotiated with difficulty and loss. As public securities are constantly the objects of transfer and sale, such obligations as represent a continually decreasing value are, from the inconvenience involved in determining that value, much less acceptable to investors than fixed or perpetual annuities. Since the time in which the public debt was consolidated, it has been the general practice of British financiers to grant permanent annuities, as nearly at the market rate of money as possible, and occasionally to add a small terminable annuity. For instance, in 1783 a loan of six millions was negotiated on the following terms: The advance of 100*l.* was to secure the contributor 100*l.* 3 per cent. consols, 50*l.* four per cent. consols, and 5*s.* 6*d.* annuity for 7½ years. At the estimate taken by the minister of the market value of these several securities, the terms of the loan were understood to be 57*l.* 12*s.* 6*d.* for the 100*l.* 3 per cents., 37*l.* 8*s.* 9*d.* for the 50*l.* 4 per cents., and 4*l.* 17*s.* 11½*d.* for the capitalised value of the long annuity. It is manifest that only a very small portion of this loan was brought immediately within the contingency of repayment.

The first sinking fund established in this country for the purpose of gradually extinguishing the permanent debt, was the work of Sir Robert Walpole, and set on foot in the year 1716. By one of the clauses in an Act passed in order to put the public debt on a more satisfactory footing, it was provided that any

FUND, SINKING

surplus arising from the aggregate, the South Sea and the General Yearly Funds, should be devoted to discharging the principal and interest of all debts incurred before December 25, 1716, according to a form directed by a future Act of Parliament, and should be employed for no other use or purpose whatsoever.

The accumulated surplus was funded, and the yearly interest added to the sum; the purpose being, that the sum invested should gradually absorb the public debt, and so secure its extinction by the machinery of compound interest. But very speedily the demand for supplies and the necessity for meeting deficiencies on the special taxes imposed, where future produce was over-estimated, led the administration to employ the sinking fund either as a guarantee for new loans, or to diminish its amount by making up the deficiency from its accumulations. Still, the aggregate of the fund was on many occasions devoted to the liquidation of the debt. At the commencement, however, of the war of 1739, the sinking fund had been diminished by more than three millions, and subjected to an annual charge of nearly 60,000*l*. At the end of the war in 1748 the sinking fund had contributed nine millions more to the costs of the war. In course of time the fund was to all intents and purposes exhausted.

In the year 1786, Mr. Pitt brought forward a measure for the re-establishment of the sinking fund on a 'new and secure basis.' In the formation of his scheme, Pitt sought the advice of Dr. Price, a Nonconformist minister of considerable mathematical capacity, who had pertinaciously advocated the necessity of adopting some plan for the reduction of the debt. Pitt's proposal was, that a million annually should be raised by loan or taxes, which should be vested in the hands of certain commissioners—namely, the Speaker, the Chancellor of the Exchequer, the Master of the Rolls, the Accountant General of the Court of Chancery, and the Governor and Deputy-governor of the Bank of England—in trust to purchase stock at the market price, and reinvesting the interest paid on such purchases, to accumulate the fund till its annual income should reach four millions, when the capital sum should be dealt with by parliament. It was imagined that this machinery would ultimately liquidate the debt; and the proposers of the scheme derived great satisfaction from certain arithmetical demonstrations as to the rapid growth of a capital which was brought within the beneficent operation of compound interest.

The purchases effected by the commissioners never accomplished more than the repurchase of loans in order to supply the annual million. In fact, then, the whole operation of the sinking fund was to create debt, and extinguish it; but there was also considerable loss in the process.

During the years 1793—1801, the average price at which stock was created was 57*l*. 7*s*. 6*d*.; that is, 100*l*. 3 per cents. were granted at this rate of payment. But the average market price of consols was 61*l*. 7*s*. 6*d*.; that is, the purchase

FUNDS, PUBLIC

of stock by the commissioners was effected at an increase of 4½ per cent. over the price at which they negotiated this annual loan, and the accumulated loss on these absurd operations amounted to 2,334,500*l*.

Between 1803 and the end of the continental war, the average price at which loans were made was 60*l*. 7*s*. 6*d*., and the average market price of consols was 62*l*. 17*s*. 6*d*. Here the loss was 2½ per cent., and the total amount of loss in the thirteen years was 4,404,331*l*., making the total loss consequent on the transactions of the sinking fund no less than 6,638,831*l*.

A considerable portion of this nominal fund was appropriated to meet the deficiency of supplies in the year 1813; and gradually the public became alive to the absurdity of the whole scheme. Dr. Hamilton of Aberdeen has the credit of being the first person who exposed the intrinsic futility of this and other similar sinking funds, and of having pointed out that no means can be employed for the reduction of public debts, other than by an excess of revenue over expenditure, and that when such an excess is in the hands of government, it is better to apply the proceeds at once to the extinction of a portion of the debt, than to attempt any of the machinery of a separate fund accumulating at compound interest.

See, for more information, *Grellier's History of the National Debt*; *Hamilton On the National Debt*; *McCulloch On Taxation and the Funding System*; and *Porter's Progress of the Nation*.

Funds, Public. The name given to the public funded debt due by government.

The practice of borrowing money in order to defray a part of the war expenditure began, in this country, in the reign of William III. In the infancy of the practice it was customary to borrow upon the security of some tax, or portion of a tax, set apart as a fund for discharging the principal and interest of the sum borrowed. This discharge was, however, very rarely effected. The public exigencies still continuing, the loans were, in most cases, either continued, or the taxes were again mortgaged for fresh ones. At length the practice of borrowing for a fixed period, or, as it is commonly termed, upon *terminable annuities*, was almost entirely abandoned; and most loans were made upon *unterminable annuities*, or until such time as it might be convenient for government to pay off the principal.

In the beginning of the funding system, the term *fund* meant the taxes or funds appropriated to the discharge of the principal and interest of loans; those who held government securities and sold them to others selling, of course, a corresponding claim upon some fund. But after the debt began to grow large, and the practice of borrowing upon perpetual annuities had been introduced, the meaning attached to the term *fund* was gradually changed; and instead of signifying the security upon which loans were advanced, it has, for a long time, signified the principal of the loans themselves.

Owing partly, perhaps, to the scarcity of dis-

FUNDAMENTAL BASS

posable capital at the time, but far more to the supposed insecurity of the revolutionary establishment, the rate of interest paid by government in the early part of the funding system was, comparatively, high. But as the country became richer, and the confidence of the public in the stability of government was increased, ministers were enabled to take measures for reducing the interest, first in 1716, and again in 1749.

During the reigns of William III. and Anne, the interest stipulated for loans was very various. But in the reign of George II. a different practice was adopted. Instead of varying the interest upon the loan according to the state of the money market at the time, the rate of interest was generally fixed at *three or three and a half per cent.*; the necessary variation being made in the principal funded. Thus, suppose government were anxious to borrow, and that they preferred borrowing in a 3 per cent. stock, while they could not negotiate a loan for less than $4\frac{1}{2}$ per cent., they effected their object by giving the lender, in return for every 100*l.* advanced, 150*l.* 3 per cent. stock; that is, they bound the country to pay him or his assignees 4*l.* 10*s.* a year in all time to come, or otherwise to extinguish the debt by a payment of 150*l.* In consequence of the prevalence of this practice, the principal of the debt now existing amounts to nearly *two-fifths* more than the sum actually advanced by the lenders.

Some advantages are, however, derivable, or supposed to be derivable, from this system. It renders the management of the debt, and its transfer, more simple and commodious than it would have been had it consisted of a great number of funds bearing different rates of interest; and it is contended that the greater field for speculation afforded to the dealers in stocks bearing a low rate of interest has enabled government to borrow, by funding additional capitals, for a considerably less payment on account of interest than would have been necessary had no such increase of capital been made. [NATIONAL DEBT.]

Fundamental Bass. In Music, the lowest note or root of a chord. [MUSIC.]

Fundamental Triangle. [COORDINATES.]

Fundus (Lat. *a basis*). In Anatomy, the base of any cone-shaped organ: the term is usually restricted to that part of the uterus, the urinary bladder, and the gall-bladder.

Funeral (Lat. *funus*). [SEPULTURE, RITES OF.]

Fungi (Lat. pl. of *fungus*, *a mushroom*). A large class of Cryptogamic plants, of low organisation, distinguished at certain points from the seaweeds more by habit than by any general character. They agree with them in their cellular structure and the almost constant absence of vascular tissue; while they differ, according to our best authorities, in their scarcely ever being aquatic, in deriving nutriment from the substance on which they grow, and in the far lower degree of development of the organs of impregnation. They are also nearly

FUNGI

allied to the class of Lichens, the latter being distinguished by producing gonidia and by deriving their nourishment from the air and not from the matrix on which they grow.

The *Fungi*, observes Mr. Berkeley, may be recognised either as the creatures of corruption—i.e. springing from various bodies, whether animal or vegetable, in a more or less advanced stage of decomposition—or as parasites of living bodies, producing an injurious change. The ephemeral toadstools of the hotbed, the mushrooms of our rich pastures, the sap-balls on decaying trees, the moulds which infest our food, and even the tissues of living animals, the mildew bunt and smut of our corn-crops, with many other more or less familiar objects, are so many *Fungi*, all agreeing in the main particulars which we have indicated, and so differing from the green scum of our brooks, and the weeds of the sea, though distinguished from each other by essential differences of structure. In some, no indications of sexual differences have been found, while in others there are bodies which in all probability have an especial sexual function, though at present we are without actual proof of the fact.

Fungi are divided into two great sections, characterised by the mode in which the reproductive bodies are formed. In the one, they are simply the terminal joint or joints of the component threads or cells, altered in form from those which precede them, and at length falling off and reproducing the plant, in which case they are called *spores*. In the other they are formed from the contents of certain sacs or asci, and are usually definite in number, in which case they are called *sporidia*. Both spores and sporidia may be multicellular, and in germination give rise to as many threads of spawn as there are cells. These curious plants are ranged in six principal divisions, variously regarded as natural orders, or tribes, namely: *Hymenomycetes*, of which mushrooms and sap-balls are well-known examples; *Gasteromycetes*, represented by the puff-balls; *Coniomycetes*, of which the rust and bunt of corn afford ready instances; *Hyphomycetes*, to which belong the naked-seeded moulds; *Ascomycetes*, of which morels and insect *Sphæria* are examples; and *Physcomycetes*, represented by the common bread mould.

The use of *Fungi* in the organised world is to check exuberant growth, to facilitate decomposition, to regulate the balance of the component elements of the atmosphere, to promote fertility and to nourish myriads of the smaller members of the animal kingdom. They occur in every part of the world where the cold is not too intense to destroy their spawn, or where there is sufficient moisture, though they abound the most in moist temperate regions. A vast number of species are known, and many of these are of great importance to man, either from their useful or their mischievous properties. The mushroom, truffle, and morel, delicacies well known at table, and the ergot, so use-

FUNGIBLES

ful in obstetric practice, are illustrations of the former; the fly agaric and other poisonous species, as well as blight, mildew, rust, and brand, and the merulius and others which induce dry rot, are examples of the latter. The reader is referred, for further information, to Berkeley's *Introduction to Cryptogamic Botany*, and *Outlines of British Fungology*; Badham's *Esculent Funguses of England*; and to the illustrated works of Gréville, Bulliard, Sowerby, Corda, Nees von Esenbeck, Tulasne, and Hussey.

Fungibles. In Scotch Law, such movable goods as may be estimated by number, weight, or measure, as corn, butter, ale, &c.

Fungic Acid. An acid contained in the juice of most fungi. It is said to be a mixture of citric, malic, and phosphoric acid.

Fungicola (Lat. fungus, a mushroom, and colo, to inhabit). The name of a family of Coleopterans, comprehending those which are found on mushrooms.

Fungiform, Fungilliformis (Lat.). In Botany, terms signifying *mushroom-headed*, applied to any bodies having a short thick figure, one end of which is much more dilated than another.

Fungin. The fleshy part of mushrooms purified by digestion in hot water.

Fungus (Lat.; Gr. σφύγγος). In Surgery, a term applied to the too luxuriant formation of flesh about an ulcer, or what is commonly called *proud flesh*.

Fungus Hæmatodes (Gr. αἱματώδης, blood-red), **Spongoid Inflammation** or **Soft Cancer**. A species of malignant tumour, called also *medullary sarcoma*.

Funicular Machine (Lat. funis, a rope). In Mechanics, if a body fixed to two or more ropes is sustained by powers which act by means of those ropes, the assemblage is called the *funicular machine*, or *rope machine*. If a rope is stretched horizontally between two points, its own weight alone will prevent it from becoming perfectly straight, whatever force be employed in stretching it; and a very small force applied at its middle point, at right angles to its direction, will be sufficient to overcome a very great resistance at the points to which its extremities are attached. In this manner a very small force may be made to raise a very great weight to a small height. This method of applying force is familiar to seamen, who frequently have recourse to it in bracing their sails.

Funicular Polygon. In Statics, the figure assumed by a string under the action of several pressures. The form of such a polygon being given, as well as the magnitudes and lines of action of the several impressed forces, the tensions which the several portions of the string have to sustain can be easily determined on the principle that the two tensions at each point where a pressure is applied must, jointly, hold the latter in equilibrium. When the forces are applied to smooth rings through which the rope passes, the tension at every point of the rope will be the same; and when equilibrium is

FURL

established, the line of action of each pressure will bisect the angle of the funicular polygon. The funicular polygon is investigated in every good treatise on Statics.

Funiculus (Lat. dim. of funis, a cord). In Botany, a prolongation of the placenta in the shape of a cord, to which the ovules are attached.

Funnel of a Steamship (Lat. infundibulum; Limousin, enfounil; Bret. founil; Wedgwood). The chimney for carrying the smoke from the furnace to a convenient height above the deck, and at the same time the channel for securing a draught for the flues. It is ordinarily of thin iron, and of considerable diameter. Modern funnels are made telescopic, so that when no great draught is necessary, they can be drawn down beyond the reach of wind or shot.

Funnel-shaped. In Botany, a term used in describing the general form of a calyx, corolla, or other organ, the tube of which is like a funnel or inverted cone.

Fur (Fr. fourrure). The coated skins of wild animals, especially of those of high northern latitudes; such as the wolf, bear, beaver, &c. The hair of fur is cleansed, and the skin is generally slightly tanned. The most valuable furs, such as ermine and sable, come chiefly from Russia. When unprepared, or merely dried, the fur skins go under the name of *peltrey*.

Furfuraceous (Lat. furfur, bran). A term applied to certain eruptions in which the cuticle peels off in scales: also to a branlike sediment which is sometimes observed in the urine.

Furfuramide. A product of the action of ammonia on furfurol.

Furfurine. When a mixture of bran, water, and sulphuric acid is distilled, the product contains a fragrant volatile oil, which has been called *furfurol* = $C_5H_4O_2$. When furfurol is acted on by ammonia, it produces a yellow crystalline substance, termed *furfuramide* = $C_{11}H_{10}O_2N$, and this, when boiled in a weak solution of potash, is converted into a basic crystallisable substance, which has been called *furfurine*, and which produces with the acids a series of crystallisable salts. Furfurine is = $C_{20}H_{18}O_2N_2$, and is a near approach to the native alkaloids. Some of its salts are bitter, and have been compared to those of quinia.

Furfurol. An oily matter formed when sugar or starch is acted upon by a mixture of sulphuric acid and peroxide of manganese.

Furies. [ERINYES; EUMENIDES.]

Furl (an old form of this word is *farthel*: furl answers to the Old Fr. fresler, to *furl*; farthel, to Old Fr. fardeler, to *truss up*: Wedgwood). In Navigation, to roll the sail up and confine it closely to the yard; the sail being gathered up by the men on the yard, the leech or edge is passed along the yard to the middle or *bunt*, where the body of the sail, the foot and clews, are collected. In this way the sails of a man-of-war are removed nearly out of view in an almost incredibly short space of time.

FURLONG

Furlong. An English measure of length, equal to the eighth part of a mile.

Furlough (Dutch, *verlof, leave*: Wedgwood). In Military language, the permission granted to a non-commissioned officer or soldier to absent himself for a given time from military duty.

Furnace (Lat. *furnus*, Ital. *forno*, Fr. *fourneau*). An apparatus wherein is placed a cavity to contain combustible matter, which in various ways is supplied with air to facilitate its combustion. The two classes into which furnaces are divided are air or wind furnaces, and blast furnaces. In the former the air is conducted through the fire by the draught of a funnel or chimney which communicates with it; in the latter, the action of bellows or some other pneumatic apparatus supplies the air. The word *furnace* has generally, however, a more circumscribed application; being applied usually to an apparatus for the fusion of metals, or to that used in a chemical laboratory. [FOUNDRY.]

Furniture (the Italian, French, and English forms of this word point to the Latin *furnus*, *an oven*: Wedgwood, *English Etymology*). In Architecture, the visible brasswork of locks, knobs to doors, window-shutters, and the like.

FURNITURE. In Printing, the materials used to extend pages of type to their proper length; also to separate them, when imposed, to a just distance from each other, so that when the sheet is printed and folded the margin shall be regular and uniform. [IMPOSING.] Furniture consists of pieces of oak wood planed up to specific thicknesses, and to about half an inch high; sidesticks and footsticks, which are placed at the outside of the pages, and made thinner at one end than the other, to allow the quoin to secure them more effectually; and quoins or wedges, usually made of beech wood, with which the pages are wedged up in a chase. Furniture smaller than two-line great primer is called *reglet*.

Furring. In Architecture, the small slips nailed on joists or rafters, where some parts of them are lower than others, or where the surface is not regular, so as to bring the boarding which they are intended to receive to the same plane.

Furunculus (Lat. from *fur*, *a thief*). A boil, or inflammation occurring in the cellular membrane beneath the skin, terminating in the formation of pus. A boil has a central core, and the pus forms in a cavity circumscribed by indurated cellular tissue. When many boils appear at once, or follow each other in rapid succession, the constitution often suffers severely, and it is advisable to pay attention to the state of the secretions, and to support the strength by tonics and good diet. In the young, or in cases in which only one boil appears, no treatment is required; but in the old who suffer from a succession of boils, much care is requisite. Eruptions of the skin characterised by the formation of small furunculi have rather indiscriminately been termed *furuncular eruptions*. [CARBUNCLE.]

FUSEE

Furze. The *Ulex europæus* of botanists, a prickly bush, found abundantly in exposed heaths in England and the more southern countries of Europe, from which it is by some supposed to have been introduced; a conjecture rendered probable by its not being able to bear the more rigorous of our winters. Its preference for sterile soil has caused it to be extensively used for fences in such land, as a cover for game and a shelter for young plantations. Its young and tender shoots are browsed upon by sheep and cattle. On some inferior soils it is cultivated with profit for these shoots; and even the older stems, when crushed, are good and wholesome fodder.

Fuscin (Lat. *fuscus*, *tawny*). A brown colouring matter obtained from empyreumatic oils.

Fuse or Fusee. In Artillery, a case of wood or metal, containing an arrangement for igniting the bursting charge in a shell. For smooth-bored guns the fuse is ignited by the gas from the powder passing round the shell; but for rifled guns by a percussion arrangement, set in action by the shock of the discharge. The fuse fits into the fuse-hole of the shell, which is sometimes furnished with a socket or bouche.

Fusee. In Watchwork, that part of the machinery about which the chain is wound, and which is immediately acted upon by the main-spring. The use of the fusee is to equalise the action of the spring. In proportion as the spring becomes unwound, its effort continually relaxes; so that if the first wheel were attached to the barrel, as is often the case in common watches, the inequality of the impelling power would produce a corresponding inequality in the rate of going. In order to correct this, one end of the chain is attached to and wound round the barrel in which the main-spring is contained; while the other end is coiled about the fusee, which has a conical shape, and is fixed on the axis of the first wheel. The principle generally adopted for determining the figure of the fusee is, that its radius, at any point to which the chain is a tangent, should be inversely as the tension of the chain in that position. Within certain limits this is nearly true; and if we assume with Hooke that the force of a spring is proportional to the distance to which it is drawn from the position of rest, and also lay aside all consideration of the length of the chain wrapt about the fusee, it would be easy to show that the fusee should be the solid generated by the revolution of the equilateral hyperbola about its asymptote. This conclusion is, however, by no means correct; but though the subject has been treated by several eminent mathematicians, very little practical advantage has been derived from their theoretical investigations. In fact, a moderate approximation to the true figure (whatever that may be) is all that can be attained in practice, and all that is necessary.

FUSEL OIL.

Fusel Oil. [FUSEL OIL.]

Fusible Calculus. That species of urinary calculus which consists of a mixture of ammonio-magnesian phosphate and phosphate of lime, and which is characterised by the facility with which it enters into fusion before the blowpipe.

Fusible Metal. An alloy of eight parts of bismuth, five of lead, and three of tin. It liquefies at a temperature below 212°. The addition of about one part of mercury or of cadmium renders it still more fusible.

Fusible Salt of Urine. A name by which the old chemists designated the *ammonio-phosphate of soda*, obtained by the evaporation of urine.

Fusiform (Lat. *fusus, a spindle*). Spindle-shaped; thickest at the middle and tapering towards the ends.

Fusil (Fr.; Ital. *foile, a fire steel for a tinder-box*). A term first met with in the seventeenth century, and applied to a light musket nearly similar to a carbine, with a flint lock. The fusil was originally used by light companies; and in the British army it has given its name to several regiments called the *fusiliers*.

Fusil (Fr. *fusée*). In Heraldry, a bearing of a rhomboidal figure more slender than the lozenge; its upper and lower angles being more acute than the two middle ones.

Fusine (Lat. *fusus, a spindle*). In Conchology, a term used for spindle shells, analogous in shape to the genus *Fusus* [which see].

Fusion (Lat. *fusio, a pouring forth*). *Aqueous* or *watery fusion* is the liquefaction by heat of salts containing water of crystallisation. *Igneous fusion* is liquefaction by heat of bodies which contain no water.

FUTURE TENSE

Fustian (Fr. *fustaine*, Ital. *fastagno*). A thick twilled cotton, of which velveten, corduroy, and thickset are varieties. [VELVET.] Fustian is generally dyed of a deep olive or lead colour.

Fustic. A yellow dye stuff. Two kinds of fustic are occasionally used by dyers. *Old fustic* is the wood of a large tree, the *Maclura tinctoria*, which grows abundantly in many parts of the West Indies and America; it gives a dingy yellow dye, chiefly useful in the production of compound colours. *Young fustic* is the *Rhus Cotinus*, or Venice Sumach, a shrub growing in Italy and the South of France; it gives a greenish-yellow dye, and is also used as an accessory material.

Fustin. The yellow colouring matter of fustic.

Futtock Plates. Flat iron bars or plates, receiving at one end the lower dead-eye of the topmast rigging, and at the other the futtock shroud.

Futtocks. In Nautical language, the timbers between the floor timbers and the top timbers.

Future Tense. In Grammar, that inflexion of the verb which expresses future time. In all Aryan languages, this inflexion is produced by a combination of the auxiliary verbs, *to have* or *to be*. Thus the Greek *τύψω*, *τυψ-σ-ω*, exhibits the root *as to be*, in combination with the root *τυψ*, *to strike*: the Latin *amabo* in the same way exhibits the root *am*, *to be*. Thus again the French *parlerai* is made up of the infinitive mood *parler*, and the present tense of *avoir*, *to have*: the Provençal forms *dir vos at*, *dir vos em*, show these elements in their genuine and uncompounded form.
